## SI-2 Experiments for the estimation of specific sampling rates

### SI-2.1. Kinetic experiments for estimating the elimination of pyrethroids/organophosphates from silicone rubber (SR)

Kinetic parameters for the exchange of pyrethroids and organophosphates between silicone rubber (SR) and water were tested by two approaches. In the first approach, a kinetic experiment in a flow channel system as described in Vermeirssen et al. (2008) was set up for testing the elimination of all analytes (targets and performance reference compounds (PRCs)) from SR sheets (Fig SI-3.1). Two flow channels were run with a flow velocity of  $0.23 \pm 0.02$  m/s. Water from the nearby Chriesbach river was pumped into a storage tank. The water was run through the channels and pumped back at a rate of  $20 \text{ m}^3/\text{h}$ . Freshwater was added at  $0.24 \text{ m}^3/\text{h}$  in order to exchange the water in the system ( $0.48 \text{ m}^3$ ) within 2 h.

**Fig. SI-2.1.** Set-up of the flow channel system.

Thirty-four SR sheets with a size of 3 x 10 cm<sup>2</sup> were loaded with a mix of all substances analogue to the method described in Smedes and Booij (2012) to achieve a concentration of approximately 1 mg/L in the final extract. For this, 15 µg of each substance was spiked into a glass bottle filled with 70 mL methanol and the 34 sheets were added. The bottle was shaken for seven days with daily addition of nanopure water up to a water content of 60%. The loaded sheets were placed into the two flow channels for different time periods. During the whole experiment, temperature was measured, flow velocities were checked and the whole system was shaded with a black cover to prevent biofouling and photolysis. At the following 17 time points, one passive sample was taken from each channel: 0, 0.5, 1, 1.5, 2, 3, 4, 7, 10, 14, 23, 30, 35, 42, 49, 56, 60 days. In addition, non-spiked samples (blank) were taken at five time points (10, 14, 35, 49, 60 days). All samples were extracted and measured with the optimized method described in the main text.

In the second approach, 28 of the 40 environmental samples from the medium sized rivers (see Fig. SI-3.1) were spiked with five pyrethroids that were possible candidates for PRCs (allethrin, imiprothrin, acrinathrin, fluvalinate, fenpropathrin, Table SI-3.2). The five pyrethroids were the only substances that are not allowed to be used in Switzerland, neither in plant protection products nor as biocide. Two concentrations were selected: 1 mg/SR sheet (30 x 10 cm<sup>2</sup>) and 0.5 mg/SR sheet (Table SI-3.2). The addition of the substances was done by spiking the exact volume of the PRC mix with 30 droplets onto the SR sheet. The sheets were dried under the hood (overnight) and were deployed for two weeks in the six medium-sized rivers. Six reference SR sheets were also spiked with the same concentration of PRC mix (Table SI-3.2). These sheets were not deployed in water, but stored in the dark at room temperature. After deployment, environmental sheets and the corresponding reference sheets were stored at -20°C and analyzed as described in the main text.

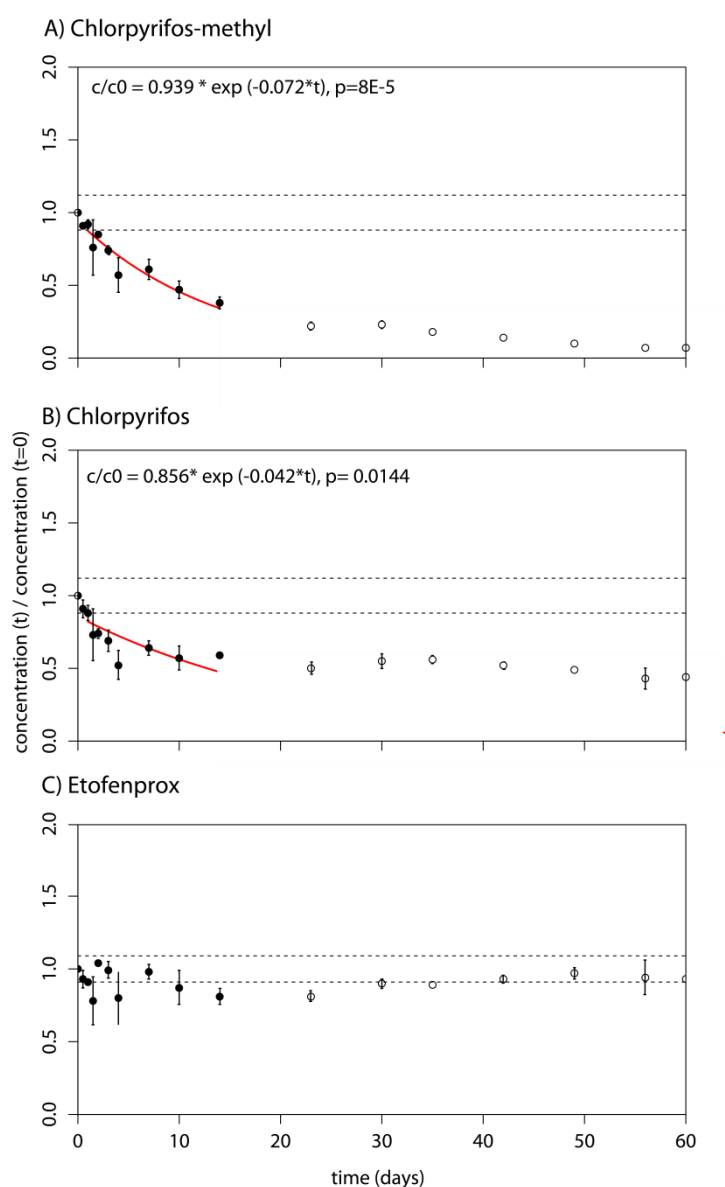

### **SI-2.2. Estimation of the elimination constant in the flow channel experiment**

Because the exchange of non-polar substances between SR and water is isotropic (Rusina et al. (2010)), the determination of an elimination constant is a possible approach to calculate sampling rates. A clear elimination of the two substances with the lowest logK<sub>ow</sub> values (imiprothrin 2.9 and chlorpyrifos-methyl 4.3, respectively) from the SR over the whole 60 days was found in the flow channel experiment (see Fig. SI-2.2 A for the example of chlorpyrifos-methyl). Substances with logK<sub>ow</sub> values above 5 (except tefluthrin) were not eliminated at all during the 60 days of the experiment (see Fig. SI-2.2 C for the example of etofenprox). Questions arise for substances with medium logK<sub>ow</sub> values such as chlorpyrifos and allethrin (5.0 and 4.8, respectively). A clear elimination was visible over the first 7-14 days (see Fig. SI-2.2 B for chlorpyrifos). After this period, however, no further elimination occurred. For chlorpyrifos, natural occurrence of the substance in the river water could be the reason for this observation (peaks in blank samples after 14 days were present), for allethrin, there must be another reason. A non-homogenous distribution in the sheet can be excluded as the substances were loaded onto the sheet by using a water/methanol mixture and not by spiking the sheets with droplets. A reduction of the diffusion due to a biofilm or chalk deposition could be another reason.

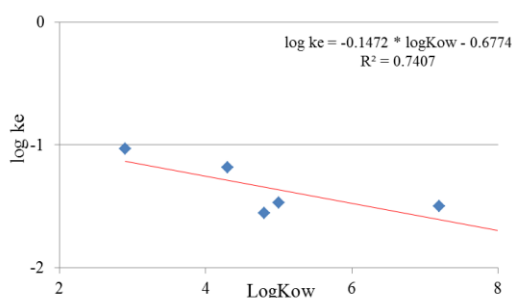

For five substances (chlorpyrifos, chlorpyrifos-methyl, imiprothrin, allethrin, tefluthrin), an elimination constant ( $k_e$ ) could be calculated for the first 14 days of deployment (see Fig. SI-2.3) by equation 1:

$$\text{Retained fraction } (f) = \frac{N(t)}{N(0)} = \exp(-k_e \times t), \quad (1)$$

where  $N(t)$  is the amount in the SR at time point  $t$  and  $N(0)$  is the initial amount of substance in the SR. A slight correlation between  $\log K_{ow}$  and  $\log k_e$  was found (Fig. SI-2.3), but much less pronounced than found for PAHs by Rusina et al. (2010).

**Figure SI-2.2.** Elimination of three substances with different  $\log K_{ow}$  values from the SR in the flow channel experiment. A) chlorpyrifos-methyl ( $\log K_{ow}$  4.3), B) chlorpyrifos ( $\log K_{ow}$  5.0), C) etofenprox ( $\log K_{ow}$  7.1). A regression could be fitted for the first 14 days (black dots) for chlorpyrifos-methyl and chlorpyrifos (red line,  $p$  equals the statistical  $p$ -value of the regression). Uncertainty bars show the standard deviation from the two flow channels.

**Figure SI-2.3.** Correlation between  $\log K_{ow}$  and  $\log k_e$  values for the five substances (imiprothrin, chlorpyrifos-methyl, chlorpyrifos, allethrin, tefluthrin) that showed an elimination within 14 days of the experiment. Red line shows the linear regression.

### **SI-2.3. Estimation of distribution coefficients between SR and water ( $K_{pw}$ )**

When  $k_e$  values are measured properly, laboratory sampling rates ( $R_s$ ) can be calculated from  $k_e$  values with the following equation (Rusina et al. (2010)):

$$R_s = k_e \times m_{SR} \times K_{pw}, \quad (2)$$

where  $m_{SR}$  is the mass of the sampler and  $K_{pw}$  is the distribution coefficient between SR and water. As  $R_s$  is directly proportional to the  $K_{pw}$  value, it is important to have accurately measured  $K_{pw}$  values (Rusina et al. (2010)). For an in-situ measurement of sampling rates, this is especially true for the substances used as PRCs. For the target substances which do not reach equilibrium within the sampling period, an estimation of  $K_{pw}$  from an empirical correlation is sufficient because the extrapolation of the sampling rate from PRCs to targets compounds only shows a weak correlation with  $K_{pw}$  (Smedes and Booij (2012), Rusina et al. (2010)). In comparison to PCBs and PAHs (Smedes et al. (2009)), for pyrethroids and organophosphates, no measured  $K_{pw}$  values exist for the material we used (Altesil<sup>TM</sup>).  $K_{pw}$  values for some pyrethroids (Hunter et al. (2009), Lao et al. (2012), Bondarenko et al. (2007)) and organophosphates (Magdic et al. (1996)) for SR from different manufacturers are available in the literature, but the values for the pyrethroids only cover a narrow  $\log K_{ow}$  range between 6 and 6.5. Difilippo and Eganhouse (2010) found that differences in  $K_{pw}$  values derived for SR from different manufacturers and between SR with different thickness are

insignificant. Nevertheless, values for pyrethroids between the three studies differed up to a factor of six. Reasons for this could be different approaches used to determine  $K_{pw}$  values. In such experiments, it is important that there is negligible depletion of the substances in the water phase, that there is no sorption to equipment and that equilibrium is reached (Difilippo and Eganhouse (2010)). No correlation between  $\log K_{ow}$  and  $\log K_{pw}$  values were found for pyrethroids. Due to different functional groups that determine the polarity of the pyrethroids, an empirical correlation can *per se* not be expected for this substance class (compared to PCBs or PAHs).

Thus, it is essential that in further studies,  $K_{pw}$  values for pyrethroids and organophosphates are measured exactly and are determined for the used material. With this information available, sampling rates under defined conditions (e.g. flow channel) can be calculated for all substances. If an empirical correlation between  $\log K_{ow}$  and  $\log K_{pw}$  exists, the extrapolated  $K_{pw}$  values can be used to determine in-situ sampling rates by using PRCs. In addition, experiments that determine the duration of linear uptake of pyrethroids/organophosphates would help for the understanding of the kinetic behavior of the investigated substances. It is possible that smaller substances are already in equilibrium after a two week deployment in the river (personal communication Kees Booij, NIOZ, The Netherlands).

#### **SI-2.4. Suitable performance reference compounds (PRCs)**

Original PRC methods focused on PRCs for which between 20-80% are retained in the sheet after the deployment time (Booij and Smedes (2010)). Often, only one substance was used as PRC in a sample. A new method, the nonlinear least squares (NLS) method, developed by Booij and Smedes (2010), makes use of multiple PRCs with different environmental properties, e.g. at least six substances covering a  $\log K_{ow}$  range of 3.5-5.5 with a distance of 0.3 log units (Smedes and Booij (2012)). The PRC must not be present in the environment,

that is, either isotope labeled substances or substances that are not allowed/used in the study area have to be selected. For substances such as PCBs and PAHs, there are enough substances from the same substance class available, either deuterated ones or substances that have not been produced in Europe. For pyrethroids and organophosphates, however, only a limited set of substances are possible candidates for PRCs. Only few isotope labeled substances are commercially available. Most of them were already used as internal standards in the analytics of this study (see main text). Five pyrethroids were selected that are not permitted in Switzerland: acrinathrin, allethrin, imiprothrin, fenpropathrin, and fluvalinate. From them, only allethrin fulfills the above mentioned  $\log K_{ow}$  criterion. The  $\log K_{ow}$  value of imiprothrin (2.9) is too low, while for the other substances it is too high ( $>5.5$ ). It is therefore very important that more suitable PRCs for pyrethroids are made available, e.g. by synthesizing more isotope labeled pyrethroids. It may also be possible that other chemical classes (e.g. PCBs) are suitable as PRCs for the determination of in-situ sampling rates of pyrethroids and organophosphates. For this, it has to be confirmed if the diffusion of pyrethroids and organophosphates are also water boundary layer controlled, as it is the case for PCBs and PAHs (Kees Booij, NIOZ, The Netherlands, personal communication).

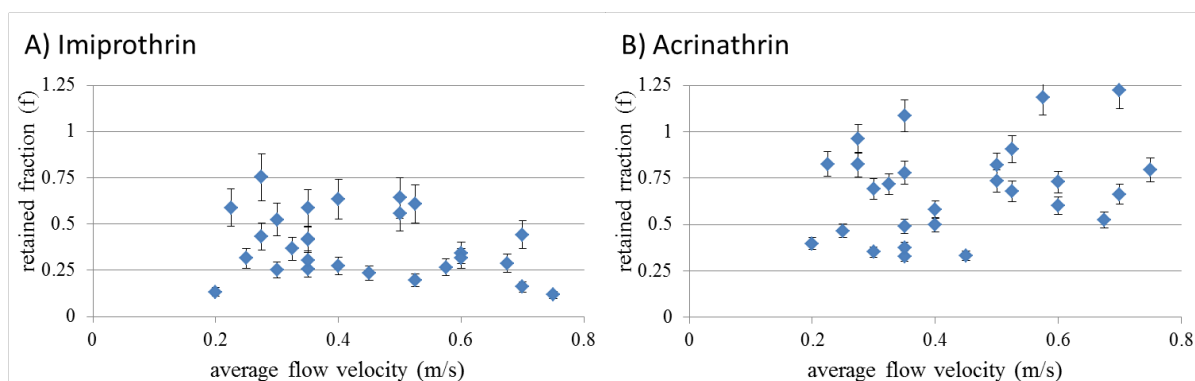

#### **SI-2.5 Elimination of PRCs from environmental samples**

In the second approach, the elimination of the five PRCs from SR sheets deployed in the environment was checked. An elimination of four of the five PRCs could be observed in most of the deployed SR sheets. For imiprothrin and allethrin, this was expected from their  $\log K_{ow}$  values, but for acrinathrin and fenpropathrin, this was not expected. No correlation between flow velocities and retained fraction was observed (Fig. 2.4 for the examples of imiprothrin and acrinathrin). A correlation was expected as the increase in flow velocity strongly increases the sampling rate (Vermeirssen et al. (2009)). It is, however, not clear up to which flow velocity an increase in the sampling rate occurs. For this, kinetic experiments should be

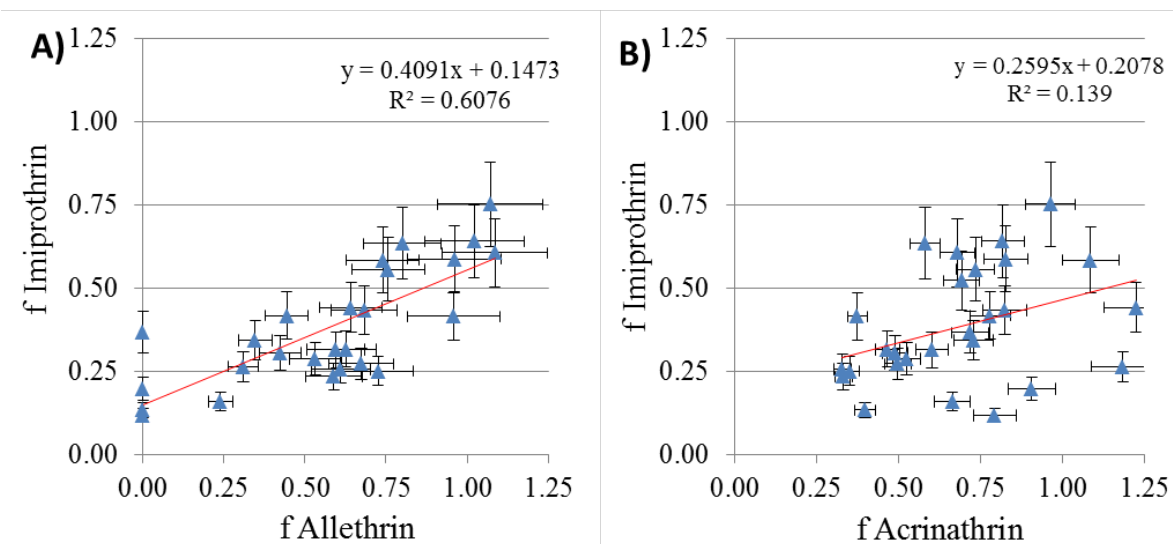

carried out at different flow velocities. Other factors than the flow velocity were expected to be less significant. Biofouling was expected to be of less relevance because the investigated samples did not show significant biofouling. The temperature increased by maximal 15°C within the five month of investigation. This should have less effect than a factor of two (Booij et al. (2002)).

There are two hypothesis why no correlation was observed and why also very non-polar substances showed an elimination in the environmental samples. First, spiking of the sheets with PRCs (dripping droplets onto sheet and let it dry overnight) could lead to an inhomogeneous distribution of the substances in the sheet. This could lead to a faster and less homogenous elimination from the sheets. It is therefore important to determine the diffusion of pyrethroids and organophosphate in the SR sheets. Previous investigations showed that the spike method is less reliable than the loading method (personal communication Kees Booij, NIOZ, The Netherlands and Markus Zennegg, Empa, Switzerland).

Second, the PRCs could have undergone photolysis in the SR sheets. An elimination of PRC due to photolysis was already described for PAHs in semi-permeable membrane devices (SPMD) by Komarova et al. (2009). As the investigated PRCs have low photolysis half-lives in water (< 14 d, see Table SI-1.1, University of Hertfordshire (2013)), the photolysis in the SR could also be of relevance. Interestingly, a correlation between the elimination of imiprothrin and allethrin was found (Fig. SI-2.5 A); these are the two substances for which a *real* desorption can be expected. It is reasonable that substance behave similar when the elimination is due to the same process. It is, however, not sure that the flow velocity was the driving factor. On the other hand, no correlation between imiprothrin and acrinathrin elimination was found (Fig. SI-2.5. B). When the acrinathrin elimination was due to photolysis and imiprothrin elimination due to desorption, it is reasonable that there is no correlation between the two substances.

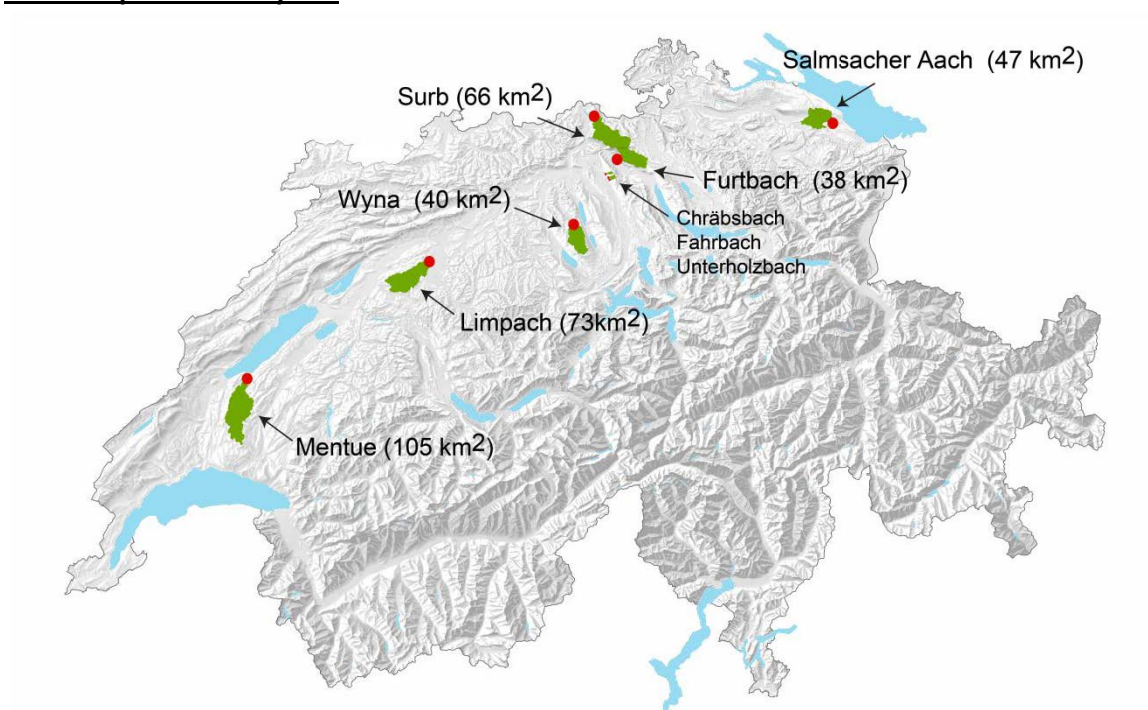

**Fig SI-2.4. Retained fraction ( $f$ ) of (A) imiprothrin and (B) acrinathrin at different flow velocities (average measurement at beginning and end of deployment) in the 28 spiked environmental samples. Error bars show the uncertainties of the analysis (see Table 1 in main text).**

**Fig SI-2.5. Comparison of the retained fraction ( $f$ ) between (A) allethrin and imiprothrin and (B) acrinathrin and imiprothrin in the 28 spiked environmental samples. Error bars show the uncertainties of the analysis (see Table 1 in main text).**

## SI-3 Field Study Information

### SI-3.3 Estimated concentrations from the measurements in the field (ng/L)<sup>1</sup>

River Name / Sample Number	Bifenthrin	Chlorpyrifos	Chlorpyrifos- methyl	Cyper- methrin	Delta- methrin	Esfenvalerat	Etofenprox	Lambda- Cyhalothrin	Permethrin	Phenothrin	Tefluthrin	Tetra- methrin
LOD (environment)	0.006	-	0.06	0.008	-	-	-	0.10	-	0.10	-	-
LOQ (environment)	0.02	0.02	0.20	0.02	0.10	0.10	0.03	0.30	0.06	0.40	0.20	0.08
Furtbach 1		0.9	0.3	0.03	0.5							
Furtbach 2		0.7	<LOQ	<LOQ	0.3							
Furtbach 3		0.9	1	0.1	1			<LOQ				
Furtbach 4		0.8	0.3	0.1	2			<LOQ				
Furtbach 5		0.6	8	0.08	0.3			<LOQ				
Furtbach 6		0.9	1	0.07	0.7			0.5				
Furtbach 8		1	6	0.1	0.5			0.4	0.4			
Furtbach 9		2	1	0.06	0.3			<LOQ	0.8			
Furtbach 10		0.9	3	0.1	0.8			0.4	0.4			
Surb 1		0.3										
Surb 2		0.4		0.03								
Surb 3		0.5		0.03					0.07			
Surb 5		0.3		0.06					0.1			
Surb 6		0.3		0.09								
Surb 8		10		0.03					0.08			
Surb 9		2		0.04					0.2			
Surb 10		0.5		0.05					0.2			
Limpach 2		0.3		0.04								
Limpach 3	<LOQ	0.4		0.05								
Limpach 4	<LOQ	0.3		0.04								
Limpach 5		0.2		0.03								
Mentue 2		0.06		0.1	0.1							
Mentue 3		0.1		0.04								
Mentue 4		0.1		0.2								
Mentue 5		0.08		0.06								
Salmsacher Aach 2		0.1	0.6									
Salmsacher Aach 3		0.4	3									
Salmsacher Aach 4		0.3	2									
Salmsacher Aach 6		0.6	1									
Salmsacher Aach 7		0.5	0.2									
Salmsacher Aach 8		0.4	3									
Wyna 2												
Wyna 3		0.1					0.2					
Wyna 4		0.04										
Chräbsbach 1												
Chräbsbach 2		0.08	<LOQ									
Fahrbach 3		1										
Fahrbach 4		0.5										
Unterholzbach 1												
Unterholzbach 2		0.5	2									

<sup>1</sup> uncertainties of the quantification: factor 3 in both directions (see main text). LOD: limit of detection, LOQ: limit of quantification. - if a signal was present in the blank samples, only LOQ was determined by 10 times the intensity of the blank value.
