## 1. General Method

All commercially available chemicals were used without further purification unless otherwise noted. Column chromatography was done with silica gel (particle size $0.063-0.200 \mathrm{~mm}$ ) and thin layer chromatography (TLC) was performed on silica gel-coated aluminum sheets with F254 indicator. All yields given refer to isolated yields. Nuclear magnetic resonance (NMR) spectra were recorded on an AVANCE 300 MHz Bruker spectrometer. Chemical shifts were reported in ppm. Coupling constants ( $J$ values) were reported in Hertz. ${ }^{1} \mathrm{H}$ NMR chemical shifts were referenced to $\mathrm{CHDCl}_{2}(5.320 \mathrm{ppm})$ or $\mathrm{C}_{2} \mathrm{HDCl}_{4}(6.000 \mathrm{ppm}) .{ }^{13} \mathrm{C}$ NMR chemical shifts were referenced to $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ (54.00 ppm). The attached proton test (APT) technique of ${ }^{13} \mathrm{C}$ NMR (J-modulated spin-echo for ${ }^{13} \mathrm{C}$-nuclei coupled to ${ }^{1} \mathrm{H}$-nuclei) was used to distinguish the carbon atoms with even or odd number of attached protons. The quaternary $(\mathrm{C})$ and methylene $\left(\mathrm{CH}_{2}\right)$ signals were in the upper phase and the methine $(\mathrm{CH})$ and methyl $\left(\mathrm{CH}_{3}\right)$ signals were in the opposite phase. Field desorption mass spectrometry (FD-MS) was carried out on a VG-Instrument ZAB 2-SE-FDP. High-resolution mass spectrometry (HRMS) was performed either on a Q-Tof Ultima 3 (micromass/Waters) by electrospray ionization (ESI) or on a SYNAPT G2 Si high resolution time-of-flight mass spectrometer (Waters Corp., Manchester, UK) by matrix-assisted laser desorption/ionization (MALDI) with tetracyanoquinodimethane (TCNQ) as the matrix. Absorption spectra were recorded on a Perkin-Elmer Lambda 900 spectrophotometer. Photoluminescence spectra were recorded on a J\&MTIDAS spectrofluorometer. The photoluminescence quantum yield $\left(\Phi_{\mathrm{F}}\right)$ was measured with 9,10 -diphenylanthracene as a standard. ${ }^{1}$

All surface-assisted experiments were performed in ultrahigh vacuum (UHV) chambers with a base pressure of $10^{-11} \mathrm{mbar}$. The $\mathrm{Au}(111)$ single crystal was cleaned by sputtering $\left(\mathrm{Ar}^{+}, 1 \mathrm{keV}\right)$ and annealing up to 750 K . The precursor $\mathbf{2}$ was thermally evaporated onto the $\mathrm{Au}(111)$ surface held at room temperature. The sublimation temperature of precursor $\mathbf{2}$ is 635 K .

Scanning tunneling microscopy (STM) and atomic force microscopy (AFM) experiments were carried out with a low-temperature scanning probe microscopy
system (LT-SPM, ScientaOmicron, Germany) at a temperature of 4.9 K. Scanning tunneling spectra ( $\mathrm{d} I / \mathrm{d} V$ ) were detected with a lock-in amplifier (HF2LI by Zurich Instruments, Switzerland). Commercial Qplus sensors ${ }^{2}$ equipped with tungsten tips (resonance frequency $=22350 \mathrm{~Hz}$, Q-factor $=11000$; tunneling current separated, ScientaOmicron) were used for non-contact AFM (nc-AFM) measurements. Repeated indentation to the substrate was used to shape the apex of the tip prior to the pick-up of a CO molecule from the sample. ${ }^{3}$ Frequency-shift images at constant height with the CO-sensitized tip were performed with an amplitude of 100 pm .

X-ray photoelectron spectroscopy (XPS) measurements were performed on the PEARL beamline of the SLS synchrotron radiation facility (Villigen, Switzerland), using linearly polarized radiation with photon energy of $425 \mathrm{eV}^{4}$. After deposition at room temperature, the sample was then transferred into the analysis chamber where the fast-XPS map was recorded during the in-situ annealing of the sample. High-resolution XPS (HR-XPS) spectra were recorded before and after the temperature ramp. XPS spectra were obtained in normal emission geometry, using a hemispherical electron analyzer equipped with a multichannel plate (MCP) detector. HR-XPS spectra were recorded in "sweep" mode with 20 eV pass energy, while the fast-XPS measurement was performed using the "fix" mode (snapshots of the C 1 s level) acquiring one spectrum every 5 s with 50 eV pass energy.

Raman spectroscopy was performed in a Bruker Senterra Raman Microscope using a 532 nm laser (corresponding to 2.33 eV excitation energy). The Raman spectra of the perihexacene analogue 1 were acquired using three scans of 60 seconds adopting 2 mW laser irradiation power; the Raman spectra of the precursor $\mathbf{2}$ were acquired using a single scan of 10 seconds adopting 0.2 mW laser irradiation power. In both cases a $50 \times$ objective lens was used, which results in a $1-2 \mu \mathrm{~m}$ spot size. The Raman spectrum of $\mathbf{1}$ was measured on the $\mathrm{Au}(111)$ surface, while the Raman spectrum of $\mathbf{2}$ was measured on the powder sample.

## 2. Procedures of Solution Synthesis

2-Bromo-3-methoxynaphthalene (4). ${ }^{5}$ To a solution of 2-methoxynaphthalene (15.8 $\mathrm{g}, 100 \mathrm{mmol}$ ) in dry THF ( 120 mL ) was added $n$ - $\mathrm{BuLi}(1.60 \mathrm{M}$ in hexane, 66.0 mL , $106 \mathrm{mmol})$ at $-78^{\circ} \mathrm{C}$ under argon. After the mixture was stirred at room temperature for 1 h, 1,2-dibromoethane ( $20.7 \mathrm{~g}, 110 \mathrm{mmol}$ ) was added at $-78^{\circ} \mathrm{C}$. The resulting mixture was then stirred at room temperature for 24 h before quenching by an aqueous $\mathrm{NH}_{4} \mathrm{Cl}$ solution. The mixture was extracted with ether $(30 \mathrm{~mL} \times 3)$ and the combined organic layers were washed with brine and water and dried over $\mathrm{MgSO}_{4}$. After removal of the solvent under reduced pressure, the residue was purified by recrystallization from hexane to give 17.5 g of compound 4 (74\%) as a white solid. ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}, 298 \mathrm{~K}, \mathrm{ppm}$ ) $\delta 8.07$ (s, 1 H ), 7.75 (dd, $J=8.3,1.4 \mathrm{~Hz}, 1 \mathrm{H}$ ), 7.71 (dd, $J=8.1,1.4 \mathrm{~Hz}, 1 \mathrm{H}), 7.47$ (ddd, $J=8.3,6.9,1.4 \mathrm{~Hz}, 1 \mathrm{H}), 7.37$ (ddd, $J=8.1$, $6.9,1.4 \mathrm{~Hz}, 1 \mathrm{H}), 7.20(\mathrm{~s}, 1 \mathrm{H}), 3.99(\mathrm{~s}, 3 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}, 298 \mathrm{~K}, \mathrm{ppm}$ ) $\delta 154.16,134.20,132.74,129.96,127.30,127.21,127.14,125.04,113.82,107.27$, 56.76. FD-MS (8 kV) m/z: Calcd for $\mathrm{C}_{11} \mathrm{H}_{9}$ BrO: 236.0; Found: 235.9 (100\%) [M] ${ }^{+}$.

1,4-Diiodo-2,3,5,6-tetra(3-methoxynaphthalen-2-yl)benzene (5). To a Schlenk flask containing activated $\mathrm{Mg}(480 \mathrm{mg}, 20.0 \mathrm{mmol})$ and 5 mL of dry THF was slowly added a solution of 2-bromo-3-methoxynaphthalene (4) (3.79 g, 16.0 mmol$)$ in 20 mL of dry THF. After the mixture was stirred at $60^{\circ} \mathrm{C}$ for 2 h , the generated Grignard reagent was transferred into a Schlenk tube charged with hexabromobenzene $(1.10 \mathrm{~g}$,
2.00 mmol ) under argon and the resulting mixture was stirred at $80{ }^{\circ} \mathrm{C}$ for 24 h . Iodine ( $3.05 \mathrm{~g}, 12.0 \mathrm{mmol}$ ) was added at $0{ }^{\circ} \mathrm{C}$ and the reaction mixture was stirred at room temperature for 2 h . After quenching with water, the mixture was extracted with chloroform for three times. The combined organic layers were washed with brine and water and dried over $\mathrm{MgSO}_{4}$. After removal of the solvents under reduced pressure, the residue was purified by column chromatography over silica gel (eluent: hexane $/ \mathrm{CH}_{2} \mathrm{Cl}_{2}=1: 1$ ), and then sonicated in 3 mL of toluene, filtrated, and washed with hexane to give 496 mg (26\%) of compound 5 as a white solid. ${ }^{1} \mathrm{H}$ NMR (300 $\mathrm{MHz}, \mathrm{C}_{2} \mathrm{D}_{2} \mathrm{Cl}_{4}, 298 \mathrm{~K}$, ppm $) \delta 8.04-6.25(\mathrm{~m}, 24 \mathrm{H}$, aromatic signals of stereoisomers), $4.20-3.45$ (m, 12H, methyl signals of stereoisomers). HRMS (ESI) $m / z$ : Calcd for $\mathrm{C}_{50} \mathrm{H}_{37} \mathrm{O}_{4} \mathrm{I}_{2}$ : 955.0781; Found: $955.0767[\mathrm{M}+\mathrm{H}]^{+}$.

5

12a,26a-Dibora-12,13,26,27-tetraoxa-benzo[1,2,3-hi:4,5,6-h'i'] dihexacene (2). To a solution of compound $5(0.14 \mathrm{~g}, 0.15 \mathrm{mmol})$ in anhydrous chlorobenzene ( 10 mL ) was added $t$ - $\mathrm{BuLi}(1.7 \mathrm{M}$ in hexane, $0.35 \mathrm{~mL}, 0.60 \mathrm{mmol})$ at $-45^{\circ} \mathrm{C}$ under argon. After stirring at $0{ }^{\circ} \mathrm{C}$ for $3 \mathrm{~h}, \mathrm{BBr}_{3}(1.0 \mathrm{M}$ in heptane, $0.40 \mathrm{~mL}, 0.40 \mathrm{mmol})$ was added at $-45^{\circ} \mathrm{C}$. The reaction mixture was stirred at $40^{\circ} \mathrm{C}$ for 24 h . After quenching with methanol, the precipitate was filtrated and washed thoroughly with methanol, water, acetone, dichloromethane, and hexane, to afford 43 mg ( $43 \%$ ) of compound 2 as a yellow solid. The solubility of $\mathbf{2}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}, \mathrm{CDCl}_{3}, 1,1,2,2$,-tetrachloroethane- $d_{4}$, toluene- $d_{8}$, DMSO- $d_{6}$, etc. was extremely low, so that even an ${ }^{1} \mathrm{H}$ NMR spectrum could not be recorded at high temperatures (up to $140{ }^{\circ} \mathrm{C}$ ). HRMS (MALDI) $\mathrm{m} / \mathrm{z}$ : Calcd for $\mathrm{C}_{46} \mathrm{H}_{24} \mathrm{~B}_{2} \mathrm{O}_{4}$ : 662.1861; Found: $662.1876[\mathrm{M}]^{+}$.

## 3. Photophysical Properties

Figure S1. Absorption and emission spectra of $\mathbf{2}$ in $\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{Cl}_{4}$ solutions. The absorption maximum is at 345 nm (absorption coefficient: $6.9 \times 10^{4} \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ ). The absorption onset is at 487 nm , corresponding to an optical energy gap of 2.55 eV . According to time-dependent density functional theory (TD-DFT) calculations, the lowest energy absorption is assigned to the HOMO $\rightarrow$ LUMO transition, whereas the absorption maximum is mainly contributed to by the HOMO $-5 \rightarrow$ LUMO transition (Figure S7). A green-yellow fluorescence was observed for compound 2, with an emission maximum at 490 nm and a quantum yield of $3 \%$.

## 4. Scanning Tunneling Microscopy

Figure S2. (a) STM image of precursor 2 deposited on $\mathrm{Au}(111)$ held at room temperature (tunneling parameters: $-2.0 \mathrm{~V}, 100 \mathrm{pA}$ ). (b) STM image of product $\mathbf{1}$ after annealing to $380^{\circ} \mathrm{C}$ (tunneling parameters: $0.6 \mathrm{~V}, 20 \mathrm{pA}$ ).

Figure S3. Separation analysis for neighboring perihexacene analogue $\mathbf{1}$ on $\mathrm{Au}(111)$. (a) Distribution map for 326 molecule pairs. (b) Histogram of the vertical separation, with highlighted areas for "abreast" (red) and "stepped" arrangement (blue). (c) Horizontal distribution of molecules in the two regions highlighted in (b) with the corresponding Gauss fits (stepped assembly in blue, abreast assembly in red). Molecular models of (d) the stepped arrangement and (e) the abreast arrangement with vertical and horizontal separation distances. The peripheral short bonds indicate $\mathrm{C}-\mathrm{H}$ bonds where the hydrogen atoms are omitted for clarity.

Both species, precursor 2 and perihexacene analogue 1, assemble into chains on the $\mathrm{Au}(111)$ surface (Figure S2). In the case of the latter the arrangement along each chain occurs in two different fashions, namely the "stepped" and the "abreast" arrangement. To investigate the differences for the two packing schemes in more detail, we measured the distances within all chains in an STM image of $120 \times 120$ $\mathrm{nm}^{2}$ (containing 73 chains, i.e., dimers to oligomers, incorporating 326 separations). Figure S3a shows the distribution map of the horizontal separation (along the chain) and the vertical separation (perpendicular to the chain) between neighboring molecules. Three distinct areas can be observed. Integrating the number of molecules with the same vertical separation reveals three clear maxima assignable to the abreast and the stepped arrangements, highlighted in red and blue, respectively (Figure S3b). A Gauss fit to the latter reveals an average separation of 0.5 nm , corresponding to an upshift of approximately two zigzag cusps, which can be associated with the formation of four $\mathrm{O} \cdots \mathrm{H}$ hydrogen bonds (up and down shifts are equivalent in case of the symmetric molecule). Next, the distances of the two species are analyzed for their horizontal separation. Figure S3c shows the two histograms and the corresponding fits to the data points, revealing a separation of 1.036 nm for the stepped and 1.125 nm for the abreast arranged molecules. With this information the bond length of the $\mathrm{O} \cdots \mathrm{H}$ hydrogen bonds present in the stepped case can be determined to be 0.19 nm and the $\mathrm{O} \cdots \mathrm{O}$ distance in the abreast case 0.40 nm . The latter translates into a $\mathrm{O}-\mathrm{Au}$ distance of 0.235 nm for the coordinating Au adatom, which is well within the range expected for metal coordination.

## 5. Scanning Tunneling Spectroscopy

Figure S4. Differential conductance ( $\mathrm{d} / / \mathrm{d} V$ ) spectra (c) of precursor 2 and perihexacene analogue $\mathbf{1}$ with the corresponding positions indicated in the STM images (a,b). Tunneling parameters: (a) $300 \mathrm{mV}, 100 \mathrm{pA}$; (b) $100 \mathrm{mV}, 30 \mathrm{pA}$.

## 6. Fast XPS Mapping

Figure S5. Fast XPS mapping for the C 1 s level of 2 deposited on $\mathrm{Au}(111)$ and annealed with a heating rate of $0.2{ }^{\circ} \mathrm{C} \mathrm{s}^{-1}$ (central panel, pass energy $=50 \mathrm{eV}$ ). High-resolution C 1s spectra (pass energy $=20 \mathrm{eV}$ ) acquired before and after the heating ramp (top and bottom panels) together with representative schemes of the molecule in the two phases. Vertical profiles representing the change of the $\mathrm{C}-\mathrm{C}$ and C-H components (blue and orange, respectively) are reported in the right panel. The $\mathrm{C}-\mathrm{O}$ component (green) and the total area of each spectrum (black) are not significantly changing during the annealing, as shown by the curves reported in the left panel.

## 7. Theoretical Simulations

7.1 Gas-phase quantum chemistry calculations. The geometries were optimized in the gas phase at the B3LYP/6-311G(d,p) level of theory using the Gaussian 09 software package. ${ }^{6}$ Frequencies were calculated for each geometry to confirm the local energy minimum or the transition state. The rate constant $(k)$ at room temperature ( 298.15 K ) was estimated using the Eyring equation ${ }^{7}$
$k=\kappa\left(k_{\mathrm{B}} T / h\right) \exp \left(-\Delta G^{\ddagger} / R T\right)$
where $k$ is the rate constant; $\kappa$ is the transmission coefficient which is taken to be unity; $k_{\mathrm{B}}$ is the Boltzmann constant; $T$ is the temperature; $h$ is the Planck constant; $\Delta G^{\ddagger}$ is the Gibbs energy of activation; $R$ is the gas constant.

Figure S6. Isomerization process of compound 2 from the twisted to the anti-folded conformation. The relative Gibbs free energies were calculated at the B3LYP/6-311G(d,p) level. As estimated from the Eyring equation, the rate constants for the forward isomerization ( $k_{\mathrm{f}}$, from twisted-2 to anti-2) and the backward reaction ( $k_{\mathrm{b}}$, from anti-2 to twisted-2) are $4.7 \times 10^{-5} \mathrm{~s}^{-1}$ and $5.8 \times 10^{-1} \mathrm{~s}^{-1}$, respectively. Therefore, the thermodynamic equilibrium constant $K\left(=k_{\mathrm{f}} / k_{\mathrm{b}}\right)$ of the forward reaction is $8.1 \times 10^{-5}$, indicating that compound $\mathbf{2}$ dominantly adopts the twisted conformation at the equilibrium state at room temperature.

Figure S7. (a) The simulated absorption spectrum of compound 2 (Gaussian line shape, half-width: 0.15 eV ) and the oscillator strengths (blue bars) by TDDFT calculations at the B3LYP/6-311G(d,p) level. The twisted conformation was used since it dominantly exists at the equilibrium state. (b) Selected molecular orbitals and energy levels of $\mathbf{2}$ calculated at the B3LYP/6-311G(d,p) level. H: HOMO; L: LUMO.

Table S1. Selected electronic transitions of $\mathbf{2}$ calculated by TDDFT method.

| Excited <br> State | Energy <br> $(\mathbf{e V})$ | Wavelength <br> $(\mathbf{n m})$ | Oscillator <br> Strength | Configuration |
| :---: | :---: | :---: | :---: | :--- |
| 1 | 2.57 | 483 | 0.1258 | $\mathrm{HOMO} \rightarrow \mathrm{LUMO}(0.70534)$ |
| 2 | 2.96 | 420 | 0.1121 | $\mathrm{HOMO}-1 \rightarrow \mathrm{LUMO}(0.69904)$ |
| 3 | 3.24 | 383 | 0.4612 | $\mathrm{HOMO}-5 \rightarrow \mathrm{LUMO}(-0.14374)$ <br> $\mathrm{HOMO}-4 \rightarrow \mathrm{LUMO}(0.47269)$ <br> $\mathrm{HOMO} \rightarrow \mathrm{LUMO}+1(0.48195)$ |
|  |  |  | 0.9707 | $\mathrm{HOMO}-5 \rightarrow \mathrm{LUMO}(0.59951)$ <br> $\mathrm{HOMO}-1 \rightarrow \mathrm{LUMO}+1(0.24188)$ <br> $\mathrm{HOMO} \rightarrow \mathrm{LUMO}+1(0.14698)$ |
|  | 3.67 | 338 | $\mathrm{HOMO} \rightarrow \mathrm{LUMO}+4(-0.11746)$ |  |

Figure S8. Frontier molecular orbitals of compounds $\mathbf{2}$ and $\mathbf{1}$ and associated energy levels according to DFT calculations at the B3LYP/6-311G(d,p) level, showing that $\mathbf{1}$ has a lower HOMO-LUMO gap than 2.
7.2 On-Surface Simulations. DFT calculations were performed using the Vienna Ab initio simulation package (VASP) ${ }^{8}$ using the projector augmented wave (PAW) method $^{9}$ and the optB86b-vdW functional, which includes long-range van der Waals (vdW) interactions. ${ }^{10}$ Considering the large size of the supercells, the $k$-point sampling was restricted to the $\Gamma$ point. A plane-wave cutoff of 400 eV was used. The vacuum regions in all the calculations were larger than $10 \AA$. We used a four layer thick rectangular $8 \times 5 \mathrm{Au}(111)$ slab in the calculations involving isolated molecules while a four layer thick rectangular $8 \times 4 \mathrm{Au}(111)$ slab was used in the calculations involving hydrogen bonded chains of precursor $\mathbf{2}$. The smallest distance between any two atoms in a molecule and its periodic image was larger than $4.5 \AA$, ensuring minimal interaction.

The energy barriers for the isomerization process of precursor $\mathbf{2}$ from the twisted to the anti-folded conformation were calculated using the climbing-image nudged elastic band (NEB) method. ${ }^{11}$ We used 16 intermediate structures in our NEB calculations. The bottom two layers in the Au slab were fixed throughout the NEB
calculations while remainder of the atomic coordinates were relaxed using a conjugate-gradient algorithm until all forces were smaller in magnitude than 0.05 eV/Å.

Table S2. Energetics of precursor 2 as single molecules. ${ }^{a}$

| Total energy (eV) |  |  |  |
| :---: | :---: | :---: | :---: |
|  | Gas phase | Substrate-supported |  |
| T | -482.73 | -659.79 | 3.75 |
| A | -482.55 | -659.82 | 3.96 |

${ }^{a} \mathrm{~T}$ : twisted conformation of $\mathbf{2}$; A: anti-folded conformation of $\mathbf{2}$.

Table S3. Energetics of hydrogen bonded chains of precursor 2. ${ }^{\text {a }}$

| Total energy (eV) |  |  | Binding energy (eV) |
| :--- | :---: | :---: | :---: |
|  | Gas phase | Substrate-supported |  |
| TT | -966.12 | -1065.59 | 7.31 |
| TA | -965.85 | -1065.95 | 7.94 |
| AA | -965.52 | -1065.88 | 8.20 |

${ }^{a}$ The chains are labeled as TT, TA, and AA depending on the conformations of the monomers in the smallest repeating units. The energies shown in this table are for the repeating units, that is, the dimers TT, TA, and AA.

Table S4. Binding energies of hydrogen-bonds in chains of precursor 2. ${ }^{\text {a }}$

|  | Gas phase | Substrate-supported |
| :---: | :---: | :---: |
| TT | 0.71 | 0.70 |
| TA | 0.69 | 0.83 |
| AA | 0.61 | 0.75 |

${ }^{a}$ The chains are labeled as TT, TA, and AA depending on the conformations of the monomers in the smallest repeating units.

Figure S9. Atomistic schematics of the hydrogen-bonded chains of precursor 2 in the (a) gas-phase and (b) substrate-supported configurations. Hydrogen bonds are depicted by black dashed lines.

Figure S10. Atomistic schematic of perihexacene analogue $\mathbf{1}$ (left) and its DFT-simulated STM image (right).
7.3 Assignment of the Main Raman Transitions. The DFT calculations of the Raman spectra of $\mathbf{1}$ and $\mathbf{2}$ reported in the main text have been carried out at the B3LYP/6-31G(d,p) level in pre-resonance conditions by using the Gaussian 09 program ${ }^{6}$ and by adopting the excitation wavelengths of 520 nm (1) and 530 nm (2). These wavelengths were selected because they best reproduced the experimental
observation after systematic inspection of the results of the simulations carried out over a wide range of excitation wavelengths ( $400-560 \mathrm{~nm}$ ). The selected wavelengths are both close to the excitation wavelength adopted in the experiments (532nm). The slight difference between the excitation wavelength selected for $\mathbf{1} \mathrm{vs} .2$ (i.e., 520 vs . 530 nm ) can be ascribed to the different experimental conditions adopted for recording the spectra of the two molecules ( $\mathbf{1}$ adsorbed on gold vs. $\mathbf{2}$ as powder). As customary, wavenumbers in all simulated spectra have been uniformly scaled by 0.98 to ease the comparison with experiments. The twisted conformation of $\mathbf{2}$ was used for these simulations since this is the expected structure of the molecule in the measured powder samples.

Figure S11. Simulated Raman spectra of (a) $\mathbf{1}$ and (b) $\mathbf{2}$ as a function of the excitation wavelength. The spectra selected for Figure 3 in the main text are drawn with green lines. The observed line shape of the $G$ band of $\mathbf{1}$ (panel a) is the result of an excitation located around $520-530 \mathrm{~nm}$ : a weak G signal is obtained for excitations below 500 nm , and above 530 nm the line shape of the G band significantly deviates from the experimental observation. In contrast, the relative intensities of the simulated spectra of $\mathbf{2}$ are less affected by the choice of the excitation wavelength around 530 nm .
graphene $\mathrm{A}_{1}{ }^{\prime} \mathrm{D}$ mode

2

Figure S12. Assignment of the D modes of 1 and 2 based on the nuclear displacements computed for graphene (adapted from the literature ${ }^{12}$ ). Red arrows (or sticks) represent displacement vectors; CC bonds are represented as green (blue) lines of different thickness according to their relative stretching (shrinking).

graphene $\mathrm{E}_{2 \mathrm{~g}}$ G-mode
(doubly degenerate)

longitudinal displacements

transversal displacements

2

Figure S13. Assignment of the G modes of $\mathbf{1}$ and $\mathbf{2}$ based on the nuclear displacements computed for graphene (adapted from the literature ${ }^{12}$ ). Red arrows (or sticks) represent displacement vectors; CC bonds are represented as green (blue) lines of different thickness according to their relative stretching (shrinking).

Figure S12 and S13 show the nuclear displacements of the normal modes of $\mathbf{1}$ and 2 assigned to the relevant observed Ramen lines. The D modes of $\mathbf{1}$ and $\mathbf{2}$ are
computed respectively at 1479 and $1378 \mathrm{~cm}^{-1}$; the associated nuclear displacement patterns at the center of the molecule closely match the characteristic D mode of graphene (Figure S12). Interestingly, the Raman spectrum of $\mathbf{2}$ shows one transversal $G$ mode $\left(\mathrm{G}_{\mathrm{t}}\right.$, computed at $\left.1572 \mathrm{~cm}^{-1}\right)$ and one longitudinal G mode ( $\mathrm{G}_{\mathrm{l}}$, computed at $1683 \mathrm{~cm}^{-1}$ ). This naming scheme has been adopted after inspecting the direction of the displacements of the $\pi$-conjugated carbon atoms with respect to the shape of the molecule (Figure S13). In molecule 1 the observed G peak is longitudinal (computed at $1659 \mathrm{~cm}^{-1}$ ) and the associated transversal component (computed at $1677 \mathrm{~cm}^{-1}$ ) is comparatively weak. The latter is predicted and observed as the higher wavenumber shoulder of the G line (see Figure 3 in the main text). Based on DFT calculations, the lower wavenumber shoulder of the $G$ line of $\mathbf{1}$ is computed at $1643 \mathrm{~cm}^{-1}$ and the associated normal mode displays a collective ring stretching pattern not directly related with graphene G mode.

## Appendix:

Cartesian coordinates obtained in gas-phase DFT calculations at the B3LYP/6-311G(d,p) level
