 (Received 20 January 2006; revised manuscript received 20 April 2006; published 25 August 2006)

We report the results of the first-principles calculation on the intermediate compounds of LiBH_4 . The stability of LiB_3H_8 and $\text{Li}_2\text{B}_n\text{H}_n$ ($n=5-12$) has been examined with the ultrasoft pseudopotential method based on the density-functional theory. Theoretical prediction has suggested that monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is the most stable among the candidate materials. We propose the following hydriding (dehydriding) process of LiBH_4 via this intermediate compound: $\text{LiBH}_4 \leftrightarrow \frac{1}{12}\text{Li}_2\text{B}_{12}\text{H}_{12} + \frac{5}{6}\text{LiH} + \frac{13}{12}\text{H}_2 \leftrightarrow \text{LiH} + \text{B} + \frac{3}{2}\text{H}_2$. The hydrogen content and enthalpy of the first reaction are estimated to be 10 mass % and 56 kJ/mol H_2 , respectively, and those of the second reaction are 4 mass % and 125 kJ/mol H_2 . They are in good agreement with experimental results of the thermal desorption spectra of LiBH_4 . Our calculation has predicted that the bending modes for the Γ -phonon frequencies of monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ are lower than that of LiBH_4 , while stretching modes are higher. These results are very useful for the experimental search and identification of possible intermediate compounds.

I. INTRODUCTION

Hydrogen is the most promising environmentally clean energy carrier to replace fossil fuels. The use of hydrogen-based energy in practical applications such as fuel cell vehicles, however, requires the development of safe and efficient hydrogen storage technology. Complex hydrides, including the light metal lithium (Li), have sufficient gravimetric hydrogen storage capacity, and a great amount of research and development about lithium complex hydrides, such as LiBH_4 (Refs. 1–3) and LiNH_2 (Refs. 4–6) has been done recently. Particularly, LiBH_4 can desorb about 14 mass % of hydrogen by the following thermal decomposition:

However, the experimental value of enthalpy of this reaction is 69 kJ/mol H_2 (Ref. 1), and LiBH_4 is too stable to release hydrogen at ambient condition. High temperature and high pressure are needed for a rehydriding reaction, so its reversibility becomes a problem for practical use.

Züttel *et al.*¹ investigated the hydrogen desorption from LiBH_4 in detail, and reported that the thermal-desorption spectra of LiBH_4 mixed with SiO_2 powder exhibited three hydrogen desorption peaks. These peaks were observed around 500, 550, and 600 K, and the products corresponded to “ $\text{LiBH}_{3.6}$,” “ LiBH_3 ,” and “ LiBH_2 ,” respectively. The compounds in quotes were nominal compositions estimated from the amount of desorbed hydrogen. This is strong evidence for the existence of the intermediate compound, and the hydrogen desorption reaction takes place in at least two steps, not a single step such as in Eq. (1). Although the low-

temperature release of hydrogen and the improvement of reversibility can be expected by the use of the intermediate compound, this has received little attention.

In this study, the stability of the intermediate compounds of LiBH_4 has been investigated theoretically and we clarify a hydriding (dehydriding) process of LiBH_4 . The thermal desorption experiment observed a structural transition around 380 K and the melting of the compound at 550 K. The stability of the solid phases at absolute zero temperature is mainly discussed here. In Sec. II, we describe the details of the computational method and the possible intermediate compounds of LiBH_4 . Section III reports the calculated results on the stability of some candidate compounds. Then, we discuss the hydriding (dehydriding) reaction via the intermediate compounds. Furthermore, the electronic structures and Γ -phonon frequencies on the most stable compound are studied. We also investigate the stability of the borane complex anions, and then compare our results with the solid compounds.

II. COMPUTATIONAL DETAILS

First-principles calculations have been performed by the ultrasoft pseudopotential method⁷ based on the density-functional theory.⁸ The generalized-gradient-approximation (GGA) formula⁹ is applied to the exchange-correlation energy.

The interaction between the ion cores and electrons is described by the ultrasoft pseudopotential,⁷ and the norm-conservation constraint¹⁰ is imposed on Li for the calculation-efficiency improvement. The scalar-relativistic all-electron calculations are first carried out on the free atoms

(ions). We chose $2s$ and $2p$ states for both Li and B pseudopotential as the reference states with the cutoff radii of 2 a.u. (Li) and 1.5 a.u. (B), respectively. A single projector function is used for each angular-momentum component. The $3d$ state is treated as the local part of the pseudopotential. The hydrogen pseudopotential is constructed from $1s$, $2s$, and $2p$ states with the cutoff radii of 1.1 a.u. (s) and 1.2 a.u. (p). We use double projector functions for the s component and a single projector function for the p component. For all pseudopotentials, the pseudowave functions and the pseudocharge-augmentation functions are optimized by a method similar to that proposed by Rappe *et al.*¹¹ Also, the partial core correction¹² is taken into account for Li and B pseudopotentials.

In the solid-state calculations, the pseudowave functions are expanded by plane waves with a cutoff energy equal to 15 hartrees. The cutoff energy for the charge density and potential is set to be 120 hartrees. The integral over the Brillouin zone is approximated by the summation on the $\mathbf{k}$ -grid elements of which the edge lengths will be as close to the target value of $0.15 \text{ \AA}^{-1}$ as possible. We confirmed that these calculation conditions gave a good convergence of energy within 0.002 eV/atom. The preconditioned conjugate-gradient technique is employed to minimize the Kohn-Sham energy functional. A procedure based on the iterative diagonalization scheme¹³ and the Broyden charge-mixing method¹⁴ is adopted in this study. Optimization of crystal structures is performed until the atomic forces and the macroscopic stresses become less than 5×10^{-4} hartree/bohr and 0.1 GPa, respectively. During the structural-optimization process, the partial occupation numbers near the Fermi level are determined by the Fermi-Dirac distribution function with $k_B T = 3 \times 10^{-3}$ hartrees. The Helmholtz free-energy functional,¹⁵ including the entropy term, is minimized instead of the Kohn-Sham energy functional. Then, the improved tetrahedron method¹⁶ is used in order to minimize the Kohn-Sham energy functional in the optimized structure. The dynamical matrix is calculated by the force-constant method¹⁷ to obtain the Γ -phonon frequencies. The atomic displacement is set to be 0.02 $\text{\AA}$. The further details of calculation are described in Refs. 2 and 13, and references therein.

As the candidates of the intermediate compounds, the existing alkali-metal B-H materials are used. For example, it is well known that boron (B) and hydrogen (H) form inorganic compounds called “borane” and the compounds of CsB_3H_8 ,¹⁸ $\text{K}_2\text{B}_6\text{H}_6$,¹⁹ and $\text{K}_2\text{B}_{12}\text{H}_{12}$ (Ref. 20) are reported. The space group of crystal structure for the compound CsB_3H_8 is $Ama2$ (No. 40) and cation Cs^+ and anion $[\text{B}_3\text{H}_8]^-$ are arranged the same as the NaCl-type structure with an orthorhombic distortion. The crystal structures of $\text{K}_2\text{B}_6\text{H}_6$ and $\text{K}_2\text{B}_{12}\text{H}_{12}$ are best described as an anti- CaF_2 -type arrangement with K^+ cation in the center of a tetrahedron formed by $[\text{B}_n\text{H}_n]^{2-}$ dianions. We first assumed that LiB_3H_8 , $\text{Li}_2\text{B}_6\text{H}_6$, and $\text{Li}_2\text{B}_{12}\text{H}_{12}$ compounds had the same crystal structures as existing CsB_3H_8 , $\text{K}_2\text{B}_6\text{H}_6$, and $\text{K}_2\text{B}_{12}\text{H}_{12}$, respectively. The stability of these candidates was evaluated using the first-principles calculations. Since the existence of a series of *closo*-type dianions $[\text{B}_n\text{H}_n]^{2-}$ ($n=5-12$) is also well known, our calculations have been expanded to $\text{Li}_2\text{B}_n\text{H}_n$ ($n=5-12$) compounds. Although the Li atom and $[\text{B}_n\text{H}_n]$ cluster are

arranged in the anti- CaF_2 -type structure and the unit-cell parameters are supposed to be a face-centered-cubic symmetry ($a=b=c$, $\alpha=\beta=\delta=90^\circ$) as starting points for the structural optimization, the output relaxed compounds have different symmetry depending on the structure of $[\text{B}_n\text{H}_n]$ clusters. The alkali-metal salt of monoclinic $\text{K}_2\text{B}_{12}(\text{OH})_{12}$ (Ref. 21) with *closo*- $[\text{B}_{12}(\text{OH})_{12}]^{2-}$ dianions has been reported, and monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ with similar crystal structure is also examined.

III. RESULTS AND DISCUSSIONS

A. Stability of candidate compounds: LiB_xH_y

Table I shows the calculated results on the structural parameters and the cohesive energies of LiB_3H_8 and $\text{Li}_2\text{B}_n\text{H}_n$ ($n=5-12$). We denote the cubic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ based on $\text{K}_2\text{B}_{12}\text{H}_{12}$ with type 1 and monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ based on $\text{K}_2\text{B}_{12}(\text{OH})_{12}$ with type 2, respectively. Compared with the cohesive energy of two type of $\text{Li}_2\text{B}_{12}\text{H}_{12}$, the value of monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ (type 2) is larger than that of type 1. Therefore, the type 2 $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is easy to form. After the next paragraph, the only result concerning monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ (type 2) is shown.

The enthalpy of formation for hydriding reactions including LiBH_4 from LiH (NaCl-type), α -B (rhombohedral), and H_2 molecule are given in Table II, where the zero-point energy corrections are not taken into consideration. They are provided using calculated cohesive energies of 2.3609 eV/atom for LiH, 6.2013 eV/atom for α -B, 2.2689 eV/atom for H_2 molecule, and 3.1501 eV/atom for LiBH_4 (orthorhombic $Pnma$ symmetry), respectively. The enthalpies of formation for $\text{Li}_2\text{B}_n\text{H}_n$ ($n=10-12$) are more negative than that for LiBH_4 . Therefore these compounds have a great potential for generating in hydriding reactions from LiH and α -B as the intermediate phase of LiBH_4 .

In order to understand the relative stability of each compound for LiBH_4 intuitively, we investigate the relation between the formation enthalpy and the mole fraction of H_2 . The enthalpy of formation corresponding to the following reaction with hydrogen of δ mole is plotted in Fig. 1:

where $\delta = (y - 1)/(2x + y - 1)$ and $x \geq 1$. This type of figure, such as Fig. 1, is often used in discussing the stability of multiphases such as the alloy system. Assuming the lines that connect each point and the origin (0,0) or (1,0) or another point, we can evaluate the enthalpy of the reaction when the $(1 - \delta)$ mole of $[\text{LiH} + \text{B}]$ and the δ mole of H_2 react and compounds LiB_xH_y are produced. From Fig. 1, monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is formed as the intermediate compound of the hydriding (dehydriding) reaction of LiBH_4 , because the actual reaction goes along the lowest state of enthalpy. Therefore, the following hydriding (dehydriding) process is proposed:

TABLE I. Structural parameters and cohesive energies (E_{coh}) of the candidate compounds: LiB_xH_y . It is denoted that the cubic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is based on $\text{K}_2\text{B}_{12}\text{H}_{12}$ with type 1 and the monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is based on $\text{K}_2\text{B}_{12}(\text{OH})_{12}$ with type 2, respectively.

The enthalpy without the zero-point energy effects and hydrogen content of the first reaction [Eq. (3)] are 56 kJ/mol H_2 and 10 mass %, and those of the second reaction [Eq. (4)] are 125 kJ/mol H_2 and 4 mass %, respectively. These results agree with the experimental ones, which reported that 9 mass % of hydrogen is liberated in the hydrogen desorption peak in the thermal desorption spectra of LiBH_4 mixed with SiO_2 -powder in Ref. 1. The enthalpy value of 56 kJ/mol H_2 for the first reaction is lower than the computational one of 75 kJ/mol H_2 for the direct dehydriding reaction of LiBH_4 [Eq. (1)].² So, the hydrogen desorption and absorption can occur at low temperature and pressure com-

paratively by using this intermediate compound.

We also calculated other possible crystal structures such as $\text{Cu}_2\text{B}_{10}\text{H}_{10}$ -type²² and $[\text{Li}(thp)_3]_2[\text{B}_{11}\text{H}_{11}]$ -type.²³ Moreover, we performed the calculation for the Γ -phonon frequencies of the candidate materials. If there was a soft mode, we lowered the crystal-structure symmetry by moving the atoms along the direction of the soft-mode eigenvectors. The maximum gain of cohesive energy was 0.03 eV/atom for $\text{Li}_2\text{B}_6\text{H}_6$; however, no compound or crystal structure more stable than monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ was found. The present calculation result on the energy of monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ provides the upper-limit value for the thermodynamic stability. In conclusion, the existence of the intermediate compound of LiBH_4 was predicted theoretically.

Recently, Kang *et al.*²⁴ have reported that LiBH and LiB are the intermediate phases of LiBH_4 , and propose the dehydriding reaction of LiBH_4 through LiBH as follows:

TABLE II. The enthalpies of formation for the hydriding reaction of various compounds LiB_xH_y , including LiBH_4 from LiH , $\alpha\text{-B}$, and H_2 molecule, where the zero-point energy corrections are not taken into consideration.

Hydriding reaction	Enthalpy of formation (kJ/mol H_2)
$\text{LiH} + 3\text{B} + \frac{7}{2}\text{H}_2 \rightarrow \text{LiB}_3\text{H}_8$	-36
$2\text{LiH} + 5\text{B} + \frac{3}{2}\text{H}_2 \rightarrow \text{Li}_2\text{B}_5\text{H}_5$	113
$2\text{LiH} + 6\text{B} + 2\text{H}_2 \rightarrow \text{Li}_2\text{B}_6\text{H}_6$	-42
$2\text{LiH} + 7\text{B} + \frac{5}{2}\text{H}_2 \rightarrow \text{Li}_2\text{B}_7\text{H}_7$	-45
$2\text{LiH} + 8\text{B} + 3\text{H}_2 \rightarrow \text{Li}_2\text{B}_8\text{H}_8$	-32
$2\text{LiH} + 9\text{B} + \frac{7}{2}\text{H}_2 \rightarrow \text{Li}_2\text{B}_9\text{H}_9$	-42
$2\text{LiH} + 10\text{B} + 4\text{H}_2 \rightarrow \text{Li}_2\text{B}_{10}\text{H}_{10}$	-87
$2\text{LiH} + 11\text{B} + \frac{9}{2}\text{H}_2 \rightarrow \text{Li}_2\text{B}_{11}\text{H}_{11}$	-79
$2\text{LiH} + 12\text{B} + 5\text{H}_2 \rightarrow \text{Li}_2\text{B}_{12}\text{H}_{12}$	-125
$\text{LiH} + \text{B} + \frac{3}{2}\text{H}_2 \rightarrow \text{LiBH}_4$	-75

We also performed the first-principles calculation of the orthorhombic phase of $Pnma$ LiBH . The reaction enthalpy for Eq. (5) is 1.30 eV per LiBH_4 formula unit (84 kJ/mol H_2), which is in good agreement with the reported value of 1.28 eV per LiBH_4 formula unit in Ref. 24. On the other hand, the reaction enthalpy of Eq. (3) is 0.63 eV per LiBH_4 formula unit. Therefore, the dehydriding reaction via the intermediate compound $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is the energetically more preferable one.

B. Intermediate compound: $\text{Li}_2\text{B}_{12}\text{H}_{12}$

Here we describe the fundamental properties, such as the crystal structure, the electronic structure, and the Γ -phonon

FIG. 1. Enthalpy of the reaction where reactants are $(1-\delta) \times [\text{LiH} + \text{B}]$ and δ mole of molecular H_2 . The plotted solid diamonds show the enthalpy of the reaction where the compound LiB_xH_y (and LiH) is produced at $\delta = (y-1)/(2x+y-1)$ mole fraction of H_2 [reaction Eq. (2) in the text]. The solid line corresponds to the enthalpy of the most stable reaction.

FIG. 2. (Color online) Crystal structure model of monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ (type 2). Large, middle, and small spheres denote Li, B, and H atoms, respectively.

frequencies, on $\text{Li}_2\text{B}_{12}\text{H}_{12}$, which is expected as the intermediate compound of LiBH_4 .

The optimized crystal-structure model of monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is shown in Fig. 2. The bond lengths between a B and H atom of $\text{Li}_2\text{B}_{12}\text{H}_{12}$ are 1.20–1.21 Å, and they are very close to those for LiBH_4 (1.23–1.24 Å) reported in Ref. 2. As for the B-B bond lengths of intra-icosahedron, the values of 1.779–1.811 Å for $\text{Li}_2\text{B}_{12}\text{H}_{12}$ are comparable to the experimental ones for the α -rhombohedral boron ($\alpha\text{-B}$) of 1.751–1.806 Å,²⁵ too. Since a boron crystal has the icosahedral B_{12} cluster as a common structural component, the decomposition of a $[\text{B}_{12}\text{H}_{12}]^{2-}$ anion into a B_{12} cluster and hydrogen molecule is easy to understand.

Figure 3 shows the total and partial density of states (DOS) for $\text{Li}_2\text{B}_{12}\text{H}_{12}$, which denotes that it has the energy gap of 5.60 eV. Since there is little contribution of the Li orbital occupied states, $\text{Li}_2\text{B}_{12}\text{H}_{12}$ consists of Li^+ and $[\text{B}_{12}\text{H}_{12}]^{2-}$ ions. The orbitals of B and H hybridize each other and the feature of occupied states in DOS is analogous with the distribution of the computed energies of the bonding molecular orbitals in $[\text{B}_{12}\text{H}_{12}]^{2-}$.²⁶

The Γ -phonon mode frequencies of monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ have been calculated so that the vibrational properties can be compared with experiments easily and directly. The phonon density of states is shown in Fig. 4. It is divided into three regions in the same case as LiBH_4 . The first region is less than 300 cm^{-1} , where the displacements of Li atoms are dominant. The second region is between 450 and 1100 cm^{-1} , where the B-H bond of $[\text{B}_{12}\text{H}_{12}]^{2-}$ dianions vibrates with a change in angle between them (bending modes), and the third region is between 2400 and 2600 cm^{-1} , where the interatomic distance of B-H bond is changing along the bond axis (stretching modes). The frequencies of bending modes are lower than LiBH_4 , described in Ref. 2, while stretching modes are higher.

The investigation using *in situ* Raman spectroscopy is effective for the confirmation of the short-range order or bonding of LiBH_4 .²⁷ We examine the atomistic vibrations of

LiBH_4 during heating by *in situ* Raman spectroscopy, and the identification of spectra modes originating from $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is now in progress.²⁸

C. Stability of complex anions: $[\text{B}_n\text{H}_n]^{2-}$

Finally, we consider the relation between the stability of the compounds $\text{Li}_2\text{B}_n\text{H}_n$ and those of complex anions $[\text{B}_n\text{H}_n]^{2-}$. The energies of the isolated $[\text{B}_n\text{H}_n]^{2-}$ are obtained using a face-centered-cubic supercell with $a=20$ Å. The single Γ point is used for the $\mathbf{k}$ -point sampling. The energies for the charged systems are computed by adding uniform background charges and improved with Makov and Payne correction²⁹ for the interaction between periodic image charges.

Figure 5 shows the comparison of the formation energies, E_f^{solid} and E_f^{complex} , corresponding to the following reactions:

and

FIG. 4. Phonon DOS for monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$. The contribution of the TO Γ -phonon modes indicated by vertical bars is only taken into account and the Gaussian broadening with a width of 30 cm^{-1} is used.

where the energies are normalized by the number of B-H pairs for comparison purposes. We can find a fairly good correlation between both energies. This is probably due to the fact that the electrostatic interaction between Li^+ and $[\text{B}_n\text{H}_n]^{2-}$ is not sensitive to n and a large part of this energy cancels out with that of LiH in Eq. (6). Among the *closo*-type dianions considered here, $[\text{B}_{12}\text{H}_{12}]^{2-}$ is the most stable one.

LiBH_4 desorbs hydrogen at temperatures above the melting point. The latent heat of fusion has been reported³⁰ to be $0.078 \text{ eV/formula unit}$ for LiBH_4 and similar values are expected for $\text{Li}_2\text{B}_n\text{H}_n$, which is considerably smaller than the energy difference between $[\text{B}_{12}\text{H}_{12}]^{2-}$ and other *closo*-type dianions. The stability of the $[\text{B}_{12}\text{H}_{12}]^{2-}$ anion supports our main conclusion in this study, that is, the intermediate phase suggested by the experiment is $\text{Li}_2\text{B}_{12}\text{H}_{12}$.

FIG. 5. Comparison of the formation energies, E_f^{solid} and E_f^{complex} , corresponding to the reactions Eq. (6) and Eq. (7) in the text, respectively, where the energies are normalized by the number of B-H pairs.

IV. SUMMARY

We have examined the stability of LiB_3H_8 and $\text{Li}_2\text{B}_n\text{H}_n$ ($n=5-12$), which are the possible intermediate compounds of LiBH_4 , by the first-principles calculation. Our computational results for the enthalpy of the hydriding reactions provide that monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is the most stable one among the candidates. The following hydriding (dehydriding) process of LiBH_4 is proposed: $\text{LiBH}_4 \leftrightarrow \frac{1}{12}\text{Li}_2\text{B}_{12}\text{H}_{12} + \frac{5}{6}\text{LiH} + \frac{13}{12}\text{H}_2 \leftrightarrow \text{LiH} + \text{B} + \frac{3}{2}\text{H}_2$. The hydrogen content of the first and the second reaction is 10 and 4 mass %, respectively, which agrees well with the thermal desorption spectra (TDS) experiment on LiBH_4 .¹ The heat of formation without zero-point energy corrections for the first reaction, which is estimated from the solid state LiBH_4 with *Pnma* symmetry (not liquid LiBH_4), is 56 kJ/mol H_2 . This value is lower than that for the direct reaction ($\text{LiBH}_4 \leftrightarrow \text{LiH} + \text{B} + \frac{3}{2}\text{H}_2$). Therefore, the low-temperature release of hydrogen can be expected by use of this intermediate compound.

We have calculated the electronic structure and the Γ -phonon frequencies of monoclinic $\text{Li}_2\text{B}_{12}\text{H}_{12}$. This compound has the energy gap of 5.60 eV and consists of Li^+ and $[\text{B}_{12}\text{H}_{12}]^{2-}$ ions. From the phonon DOS, it is predicted that its bending modes have lower frequencies than that of LiBH_4 ,² while stretching modes are higher. The identification of the experimental Raman-spectra modes originating from $\text{Li}_2\text{B}_{12}\text{H}_{12}$ is now in progress.

The stability of *closo*-borane complex anions $[\text{B}_n\text{H}_n]^{2-}$ was also examined. We found a fairly good correlation between the formation energies of the solid phases and the isolated dianions. This result supports the validity of the intermediate compound indicated in the TDS experiment being $\text{Li}_2\text{B}_{12}\text{H}_{12}$.

There are various kinds of borane, such as *nido*-type $[\text{B}_n\text{H}_{n+4}]$ and *arachno*-type $[\text{B}_n\text{H}_{n+6}]$, in addition to *closo*-type borane $[\text{B}_n\text{H}_{n+2}]$.³¹ The *nido* and *arachno* borane are derived from *closo* borane by removing one and two vertices, respectively. These generate the salts in the ionized state as well as *closo*-type dianions. These alkali-metal salts are also the candidates of the intermediate compound of LiBH_4 . We will study the details of the hydriding (dehydriding) process for LiBH_4 , including the stability of these materials, in the future.
