Recent experimental progress in the fields of cold quantum gases and ultrafast optical spectroscopy of quantum materials allows us to controllably induce and probe nonadiabatic dynamics of superconductors and superfluids. The time evolution of the gap function before relaxation with the lattice is determined by the superposition of coherently evolving individual Cooper pairs within the manifold of the Bardeen-Cooper-Schrieffer (BCS) wave function. While dynamics following an abrupt quench of the pairing interaction strength in the single-band BCS model has been exactly solved due to the integrability of the model, the dynamics of postquench multiband superconductors remain under scrutiny. Here, we develop a generalization of the Volkov-Kogan Laplace-space perturbative method that allows us to determine the nonadiabatic gap dynamics of two-band fully gapped superconductors for a wide range of quench amplitudes. Our approach expands the long-time dynamics around the steady-state asymptotic value of the gap, which is self-consistently determined, rather than around the equilibrium value of the gap. We explicitly demonstrate that this method recovers the exact solution of the long-time gap dynamics in the single-band case and perfectly agrees with a numerical solution of the two-band model. We discover that dephasing of Cooper pairs from different bands leads to faster collisionless relaxation of the gap oscillation with a power law of $t^{-3/2}$ instead of the well-known $t^{-1/2}$ behavior found in the single-band case. Furthermore, the gap oscillations display beating patterns arising from the existence of two different asymptotic gap values. Our results have important implications to a variety of two-band superconductors driven out of equilibrium, such as iron-based superconductors, MgB$_2$, and SrTiO$_3$.

I. INTRODUCTION

Superconductors that are perturbed into a state away from equilibrium display an extremely rich and interesting dynamical behavior. This originates from the interplay between the dynamics of its fermionic quasiparticle excitations and that of the superconducting order parameter, as expressed, for example, in the superconducting gap equation. Close to equilibrium, various collective modes emerge such as the Anderson-Bogoliubov phase mode [1] and the longitudinal Schmid (or Higgs) amplitude mode [2,3], which describe phase and amplitude fluctuations of the order parameter. The transverse Carlson-Goldman mode describes the coupled oscillations of normal currents and supercurrents [4,5], whereas in multigap superconductors additional Leggett phase modes appear [6], corresponding to oscillations of the relative phases of the different gaps. Interesting dynamics also occurs farther away from equilibrium, where one observes, for example, intriguing nonlinear behaviors such as dynamic instabilities towards slowly damped [7,8] or even undamped order parameter oscillations [9–12].

Generally, the dynamic response of a superconductor depends on the type of perturbation that is applied, for example, whether it is adiabatic or nonadiabatic, linear or nonlinear, and whether it is charge neutral or charged. It also depends on the hierarchy of a number of important timescales such as the quasiparticle energy relaxation time $\tau_\varepsilon$, the dynamical scale of the superconducting order parameter $\tau_\Delta$, the timescale of the external perturbation $\tau_{pert}$, and the characteristic observation time $\tau$ [13–15]. Here, we are interested in the case of $\tau_\Delta \ll \tau_\varepsilon$ and in fast, nonadiabatic perturbation occurring on a timescale $\tau_{pert} \ll \tau_\Delta \approx \tau$. This nonadiabatic, collisionless regime has been explored in a linearized approach close to equilibrium in the seminal work by Volkov and Kogan [7], who studied the gap dynamics of a single-band superconductor following a small and instantaneous perturbation. They found coherent gap oscillations that are only algebraically damped $\propto t^{-1/2}$, analogous to Landau damping in a collisionless plasma [16,17]. More recently, experimental progress on two distinct fronts have brought renewed interest to this field: (i) Ultrafast optical studies in the terahertz regime have unveiled nonadiabatic, coherent gap dynamics in thin superconducting films [18], for example, in NbN [19–22] and Nb$_3$Sn [23–25]; (ii) Cold-atom realizations of superfluids and Bose-Einstein condensates have provided a fruitful avenue to induce nonadiabatic dynamics by performing rapid parameter changes such as quenching the pairing interaction strength [26,27].

The situation of a rapid parameter quench is theoretically particularly interesting as it is amenable to analytical approaches. Going beyond the linear analysis of Volkov and Kogan and exploiting the integrability of the Bardeen-Cooper-Schrieffer (BCS) Hamiltonian [28–30], a number of works have explored postquench nonadiabatic dynamics of single-band BCS superconductors far away from equilibrium.
It was discovered that nonequilibrium dynamics at times \( t \ll \tau \ll \epsilon \) fall into one of three distinct classes (or phases) [12,34], which can be topologically distinguished by the number of complex roots of the spectral polynomial [10,11]: phase I, where the gap decays exponentially to zero; phase II, where the gap oscillates with frequency \( 2\Delta_\infty \) and decays algebraically \( \propto t^{-1/2} \) to a finite value \( \Delta_\infty \); and phase III, where persistent undamped gap oscillations occur. Phase II in the nonequilibrium quench phase diagram [12,34] contains the linear regime around equilibrium studied by Volkov and Kogan [7]. Finally, we note that the topological classification explains why terahertz induced gap dynamics is qualitatively similar to the case of a parameter quench, as has been observed in various numerical studies [24,35–39].

In this paper, we extend these previous studies by addressing numerically and analytically the gap dynamics of two-band superconductors following an interaction quench. Our motivation is on the fact that multiband superconductivity is realized in a variety of materials with conventional and unconventional pairing mechanisms. Primary examples are MgB\(_2\) [40], the iron-based superconductors [41], Sr\(_2\)RuO\(_4\) [42], heavy fermions [43], strontium titanate [44,45], and oxide heterostructures such as LaAlO\(_3\)/SrTiO\(_3\) [46]. Unconventional multiorbital superfluidity has also been reported in cold-atom setups on the honeycomb lattice [47]. While different superconducting gap symmetries are possible in the presence of multiple Fermi surfaces, we will focus on the simplest case of \( s \)-wave superconductivity. As the quench dynamics is identical for \( s^- \) and \( s^+ \) pairing, corresponding to gaps with opposite or same signs on the two Fermi surfaces, respectively, our results apply to both cases. Quenches in two-band \( s \)-wave superconductors have so far only been studied numerically [39,48,49], focusing on the coupling between the Higgs and the Leggett mode [48] or the competition between superconductivity and spin-density wave order [49]. Generalizations to quenches between other pairing symmetries such as time-reversal symmetry breaking \( s +i s \) or \( s + i d \) pairing are interesting avenues for further work. Indeed, a recent numerical study of terahertz induced gap dynamics for \( s + i s \) pairing has revealed an unusual coupling between the Higgs amplitude and the Leggett (relative) phase mode [50].

Exact solutions of the time-dependent two-band BCS model only exist for special fine tuned values of the intra- and interband interaction parameters, where the problem effectively reduces to the single-band case (see below and Ref. [49]). It is an open question whether the generic two-band BCS model is integrable. Here, we develop a generalization of the Volkov-Kogan Laplace-space analysis in order to investigate the nonadiabatic postquench dynamics in generic two-band BCS models. Like Volkov and Kogan we solve linearized equations of motion in Laplace space, but an important distinction of our work is that we expand around the long-time steady state of the system instead of the equilibrium state. This allows us to explore the gap dynamics away from the weak-quench limit in a larger region of the nonequilibrium phase diagram. We achieve this methodological advancement by self-consistently solving for the steady-state value of the superconducting gap \( \Delta_\infty \). We show in detail that our method reproduces the exact solution in phase II of the single-band model. For the two-band model we carefully check our analytical results by comparing to the numerical solution of the dynamics. We find that the oscillatory gap dynamics exhibits pronounced beating behavior due to the presence of two asymptotic gap values \( \Delta_{1,\infty} \) and \( \Delta_{2,\infty} \), which has been previously reported in a numerical investigation of terahertz driven gap oscillations in two-band superconductors [39]. A central new result of our work is that the decay of the gap oscillations due to Landau damping in two-band superconductors is governed by a power law \( \propto t^{-3/2} \) that is different from the one found in the single-band case, where it is \( \propto t^{-1/2} \) (see Fig. 1). Earlier numerical studies of multigap superconductors have reported power-law decays of \( t^{-1/2} \), although in that case the dynamics was driven not by an interaction quench, but by laser pulses [39]. Interestingly, faster than \( t^{-1/2} \) decay was also seen in the case of superconducting nanowires, where electronic sub-bands arise due to confinement [51]. Finally, a similar \( t^{-3/2} \) decay of the pairing amplitude has been found in quenches into the strong pairing [Bose-Einstein...
condensation (BEC) regime in three dimensions, but by a different microscopic mechanism [32,52].

The remainder of the paper is organized as follows: in Sec. II, we define the two-band BCS model and formulate it in terms of Anderson pseudospins. We then derive equations of motion of the pseudospins that govern the nonadiabatic dynamics of individual Cooper pairs and the gap following an instantaneous quench of the BCS coupling strength. In Sec. III, we present numerical solutions of the gap dynamics in the regime of weak quenches, which show the main features of oscillatory beating and algebraic decay $\alpha \approx t^{-3/2}$. In Sec. IV, we present our main analytical calculation and flesh out the details of our method to find the long-time dynamics of the gap using a self-consistent Laplace analysis. In Sec. IV A, we derive linearized equations of motion around the long-time steady state. We present the solution of these equations in Laplace space in Sec. IV B, which depends on the steady-state values of the gap $\Delta_{\alpha, \infty}$ and the pseudospins $N_{\alpha, \infty}$. These values are determined in Sec. IV C by solving self-consistent equations via an ansatz for the nonequilibrium distribution function in the steady state. We first show that our method yields the exact solution in the single-band model, and then apply it to the two-band case, where only numerical solutions are available. Finally, in Sec. IV D, we discuss the long-time gap dynamics in real time by performing an inverse Laplace transformation. We explicitly show how the new power-law decay exponent emerges from a distinct analytical structure of the gap in Laplace space and demonstrate how one recovers the single-band result. We conclude in Sec. V, and present additional details of our analytical calculations in the Appendixes.

II. BCS MODEL AND QUENCH PROTOCOL

A. Pseudospin formalism for equilibrium two-band superconductors

We start from the reduced BCS Hamiltonian [53] for two-band superconductors

$$
H_{\text{BCS}} = \sum_{\mathbf{k}, \sigma, \alpha} \varepsilon_{\mathbf{k}, \sigma} c_{\mathbf{k}, \sigma, \alpha}^\dagger c_{\mathbf{k}, \sigma, \alpha} + \frac{1}{N} \sum_{\mathbf{k}, \mathbf{p}, \sigma, \beta} V_{\alpha \beta} c_{\mathbf{k}, \sigma, \alpha}^\dagger c_{-\mathbf{k}, \sigma', \alpha} c_{-\mathbf{p}, \sigma, \beta} c_{\mathbf{p}, \sigma', \beta},
$$

(1)

where $\alpha, \beta \in \{1, 2\}$ are the band indices, $\varepsilon_{\mathbf{k}, \sigma}$ is the electronic dispersion near the Fermi level in band $\alpha$ (including the chemical potential), and $V_{\alpha \beta}$ is the effective pairing interaction between band $\alpha$ and band $\beta$. Although not important in the following, one may assume parabolic dispersions, $\varepsilon_{\mathbf{k}, \sigma} = k^2/2m - \mu$. The interaction constants $V_{\alpha \beta}$ are positive (negative) if the interaction is repulsive (attractive). In multiband systems, different bands develop different values of the superconducting gap, depending on the values of the intraband interactions, $V_{11}$ and $V_{22}$, and the interband interactions, $V_{12}$ and $V_{21}$ [see Fig. 2(a)] as well as the density of states of the two bands at the Fermi level, $N_{\alpha}$. We assume that the two bands have the same intraband electronic interactions such that $V_{11} = V_{22} = U$; by definition, $V_{12} = V_{21} = V$. Due to the different density of states $N_{1} \neq N_{2}$, electrons in different bands experience different effective interaction strengths. The BCS gap equation is therefore band dependent:

$$
\Delta_{\alpha} = \Delta_{\alpha}^0 + i\Delta_{\alpha}^0 = -\frac{1}{N} \sum_{\mathbf{p}, \beta} V_{\alpha \beta} \langle c_{-\mathbf{p}, \downarrow, \beta} c_{\mathbf{p}, \uparrow, \beta} \rangle.
$$

(2)

Going from summation over momenta to integrations over energy using the density of states, we write the equilibrium BCS gap equations explicitly in matrix form in the band space.

$$
\begin{pmatrix}
\Delta_1 \\
\Delta_2
\end{pmatrix} = \hat{\gamma} \begin{pmatrix}
\int_{-\Lambda}^{\Lambda} d\varepsilon \frac{\Delta_2}{\Delta_1} \tanh \left( \frac{\varepsilon}{2T} \right) \\
\int_{-\Lambda}^{\Lambda} d\varepsilon \frac{\Delta_1}{\Delta_2} \tanh \left( \frac{\varepsilon}{2T} \right)
\end{pmatrix}.
$$

(3)

where $\Lambda$ is a high-energy cutoff and

$$
\hat{\gamma} = \begin{pmatrix}
\frac{r}{1} & -\eta \\
-\eta & r
\end{pmatrix}
$$

(4)

with $\eta = N_{2}/N_{1}$ being the ratio of the density of states of the two bands, $E_\alpha = \sqrt{\varepsilon^2 + \Delta_{\alpha}^2}$ is the Bogoliubov quasiparticle dispersion in band $\alpha$ and $T$ is the temperature of the system. In the following, we restrict our analysis to the $T = 0$ ground state as the initial quench state of the system. We have also defined the dimensionless interband interaction coupling constant $v = VN_{1}$, and the dimensionless ratio $r = -U/V$ between intraband and interband interactions. Here, we include the minus sign in the definition, as we will assume that $U < 0$ is negative, corresponding to attractive intraband interaction.

Note that the ratio of the density of states in the two bands, $\eta = N_{2}/N_{1}$, determines the relative sizes of the superconducting gaps of the two bands. If the two bands have the same density of states near the Fermi energy, i.e., $\eta = 1$, the matrix $\hat{\gamma}$ becomes symmetric. Therefore, the gap equations are solved by $\Delta_1 = -\Delta_2$ for repulsive interband interaction ($v > 0$), corresponding to $s^{+}$ pairing, and $\Delta_1 = \Delta_2$ for attractive interband interaction ($v < 0$), corresponding to $s^{+}$ pairing. In this paper, we will focus on the case with $\eta \neq 1$, in which case the amplitude of the two gaps is different in equilibrium $|\Delta_1| \neq |\Delta_2|$ and the multiband nature of the system has a pronounced imprint on the nonequilibrium dynamics of the superconducting gap.

It is convenient to use the pseudospin formalism [1] to study the nonequilibrium dynamics of the superconducting state. In the mean-field approach, which is exact in the BCS regime we consider here, the BCS Hamiltonian can be
described by pseudospins exposed to an effective magnetic field:
\[ H_{\text{BCS}} = -\sum_{k,\alpha} B_{k,\alpha} \cdot \hat{S}_{k,\alpha} + \text{const.} \] (5)

supplemented by the self-consistent equation:
\[ \Delta_{\alpha} = -\frac{1}{N} \sum_{k,\beta} V_{\alpha\beta} S_{k,\beta}. \] (6)

Here, \( B_{k,\alpha} = 2(\Delta_{\alpha}', -\Delta_{\alpha}', -\epsilon_{k,\alpha}) \) and
\[ S_{k,\alpha}^- = c_{k,\downarrow,\alpha} c_{k,\uparrow,\alpha}, \] (7)
\[ S_{k,\alpha}^+ = c_{k,\uparrow,\alpha}^\dagger c_{k,\downarrow,\alpha}, \] (8)
\[ S_{k,\alpha}^0 = \frac{1}{2} (c_{k,\uparrow,\alpha}^\dagger c_{k,\downarrow,\alpha} + c_{k,\downarrow,\alpha}^\dagger c_{k,\uparrow,\alpha} - 1). \] (9)

The constant term contributes to the condensation energy, which will be ignored because it is not relevant to the dynamics out of equilibrium. The mapping between pseudospins and electronic pair operators is summarized in Fig. 2(b). The anticommutation relation between the electronic operators ensures the spin commutation relation between \( \hat{S}_{k,\alpha} \). Notice that despite the simple form of the pseudospin Hamiltonian, the effective magnetic field is self-consistently determined by the pseudospins collectively via the gap equation (6), where \( S_{k,\alpha}^- = \langle \hat{S}_{k,\alpha}^- \rangle = (c_{k,\downarrow,\alpha} c_{k,\uparrow,\alpha}) \).

In equilibrium, the pseudospins are parallel to the effective magnetic field. It is convenient to work in a gauge where both the gaps are real. Then the expectation values of the pseudospins at temperature \( T \) are given by
\[ S_{k,\alpha}^+ = \frac{\Delta_{\alpha}}{2E_{\alpha}} \tanh \left( \frac{E_{\alpha}}{2T} \right) \] (10a)
\[ S_{k,\alpha}^- = 0 \] (10b)
\[ S_{k,\alpha}^0 = -\frac{\epsilon_{k}}{2E_{\alpha}} \tanh \left( \frac{E_{\alpha}}{2T} \right). \] (10c)

Note that the length of the pseudospins in equilibrium is determined by the Fermi-Dirac distribution, \( n_{\text{f}} \), of the Bogoliubov quasiparticles, i.e., \( |\hat{S}_{k,\alpha}| = \frac{1}{2} - n_{\text{f}} \). As mentioned above, we will focus hereafter on initial prequench states at zero temperature (\( T = 0 \)).

B. Equations of motion for the pseudospins

We consider the situation where the system is driven out of equilibrium by a sudden quench of the pairing interaction. Previous studies have shown that the gap dynamics following a quench is similar to the gap dynamics following a short pump pulse [54–56]. This was numerically demonstrated in detail in Ref. [54]. It was also shown analytically within perturbation theory of the electromagnetic field, both for single and multiband superconductors [55,56]. Thus, postquench dynamics can be realized experimentally. Specifically, we focus on a sudden change of the interband coupling \( v_i \rightarrow v_f \) while keeping the ratios between intra- and interband interactions, \( r = U/V \), and between the densities of states, \( \eta \), unchanged, i.e., \( r_i = r_f \) and \( \eta_i = \eta_f \). The subscript \( i \) and \( f \) denote the initial and final values of the respective dimensionless constants.

Note that this requires quenching both intra- and interband interactions \( U \) and \( V \) in such a way to keep their ratio \( r \) fixed. We focus on these quench protocols to constrain the parameter space. Generally, one can also consider quenches of \( r \), however, this is expected to not lead to qualitative changes to the nonequilibrium dynamics, as it corresponds to a different way to prepare the initial conditions.

If the two bands have different densities of states, i.e., \( \eta \neq 1 \), the quench dynamics is intrinsically different from single-band systems. In the pseudospin formalism, the superconducting gap determines the intrinsic frequency of the pseudospin precession. Therefore, once the two bands have different densities of states, they develop different values of the gap, leading to two distinct intrinsic frequencies. In addition, the gap also serves as the effective magnetic field that drives the precession. Through the interband interaction, each band experiences an oscillating magnetic field with the intrinsic frequency of the other band. Hence, the dephasing of the pseudospin oscillations in multiband systems is fundamentally different from single-band systems. The dynamics is described by two sets of equations of motion for the two bands, which are derived from Eq. (5) in terms of expectation values of the pseudospins operators,
\[ \frac{d}{dt} S_{k,\alpha}(t) = S_{k,\alpha}(t) \times B_{k,\alpha}(t). \] (11)
which are similar to the one-band case, but now with an extra band index \( \alpha \). More importantly, the pseudospin dynamics in the two bands are coupled via the gap equations with a time-dependent interband coupling strength \( v(t) = v_i \theta(-t) + v_f \theta(t) \):
\[ \Delta_{\alpha}(t) = v(t) \sum_{\beta} V_{\alpha\beta} \int d\epsilon \sigma^{-}_{\beta}(\epsilon, t). \] (12)

The equations of motion for the pseudospins, Eq. (11) and the time-dependent gap equation, Eq. (12), determine the postquench gap dynamics of two-band superconductors.

In the following, we first solve these equations numerically and describe our results. Then, we analytically find the long-term asymptotic behavior of the gap oscillations using Laplace transforms. We develop a generalization of the well-known procedure pioneered by Volkov and Kogan in Ref. [7] (see also Refs. [32,34]). By expanding around the long-time nonequilibrium pseudospin steady state, instead of the final equilibrium state, we are able to not only determine the power-law decay of the gap oscillations, but also the steady-state nonequilibrium gap values \( \Delta_{+,\infty} \). We also explicitly show how our solution approaches the known single-band result as \( \eta \rightarrow 1 \).

III. NUMERICAL RESULTS FOR THE POSTQUENCH GAP DYNAMICS

We solve the equations of motion (11), together with the gap equation (12), numerically using the Runge-Kutta method. We focus on the weak-quench limit, to later compare with our analytical expansion. Results for two different ratios of initial and final intergap couplings \( v_i/v_f = 0.95 \) and 0.9 (with fixed \( v_f = 0.2 \)) are shown in Fig. 3. The other parameters are kept fixed: \( r_i = r_f = 0, \eta = 0.8, T_i = 0. \)
FIG. 3. Numerical results for the gap oscillations in two-band superconductors. (a)–(d) are the results for an interaction quench from $v_i = 0.19$ to $v_f = 0.2$. (e)–(h) correspond to an interaction quench from $v_i = 0.18$ to $v_f = 0.2$. (c) and (g) are the Fourier spectrums of the gap oscillations. (d) and (h) shown the $t^{-3/2}$ damping of the gap oscillations in a log-log plot. The ratio of the density of states between the two bands is $\eta = 0.8$ in these calculations.

In equilibrium, this corresponds to the following gap ratios $\Delta_{1,i}/\Delta_{2,i} = -0.8852$ for $v_i = 0.19$, $\Delta_{1,i}/\Delta_{2,i} = -0.8857$ for $v_i = 0.18$ and $\Delta_{1,f}/\Delta_{2,f} = -0.8847$ for $v_f = 0.2$. The figure contains both the time traces of the gap oscillations as well as their Fourier transforms.

There are two important qualitative features that emerge in the two-band case: first, the gap oscillations are characterized by two frequencies, corresponding to the steady-state values $\Delta_{1,\infty}$ and $\Delta_{2,\infty}$. This leads to pronounced beating when these two frequencies are sufficiently close to each other. This phenomenon has been described previously in numerical studies of two-band (multiband) superconductors exposed to terahertz laser pulses [39,48,51]. Second, the algebraic decay of the gap oscillations ($\propto t^{-3/2}$) occurs more rapidly than in the single-band case. We numerically determine the exponent to be $\alpha_{2\text{-}}\text{band} = 3/2$ as opposed to $\alpha_{1\text{-}}\text{band} = 1/2$.

This power-law behavior is insensitive to the value of $r$, as we demonstrate in Fig. 4, where we compare the dynamics of $\Delta_1(t)$ for the cases $r = 0.5$ and $r = 0$. The other parameters used were $v_i = 0.19$ and $v_f = 0.2$. We note that an exponent of $\alpha = 3/2$ also emerges if one considers deep quenches into the Bose-Einstein condensate (BEC) regime in a three-dimensional system [32,52].

IV. LONG-TIME ASYMPTOTIC GAP DYNAMICS

In order to gain more insights on the transient dynamics of the superconducting gap in two-band systems, it is instructive to have analytic solutions for the superconducting gap evolution. The gap dynamics in single-band conventional superconductors with isotropic gap structures can be solved exactly due to the integrability of the BCS model [10–12,28,30–33].
The two-band BCS model doubles the number of degrees of freedom compared to the single-band model. Due to the coupling between the two distinct bands, the integrals of motion that were constructed previously for the single-band BCS model [32,33] do not commute between the two bands, except in the symmetric case $\eta = 1$. In the single-band case, it was determined that there are three different phases depending on the strength of the quench $\Delta_1/\Delta_f$: in phase I, corresponding to $\Delta_1/\Delta_f > e^{\pi/2}$, the gap asymptotically approaches zero in an exponential fashion; in phase II, for $e^{-\pi/2} < \Delta_1/\Delta_f < e^{\pi/2}$, the gap shows damped $t^{-1/2}$ oscillations around one asymptotic value; and in phase III, which takes place for $\Delta_1/\Delta_f < e^{-\pi/2}$, the gap shows persistent oscillations between two asymptotic values.

Whether the two-band BCS model is integrable or not is beyond the scope of this work. Given the difficulties in finding the integrals of motion of the two-band case, in this section we employ instead a perturbative method to extract the long-time asymptotic dynamics of the superconducting gap in phase II, where the gap shows damped oscillations. This precisely the behavior found numerically for weak quenches, shown in Fig. 3. In particular, the method we develop here is a modified version of the one pioneered by Volkov and Kogan in Ref. [7], which allows us to also analytically determine the steady-state gap values $\Delta_{a,\infty}$.

Note that the Volkov-Kogan method has also been applied to the case of one-band and two-band superconductors excited by monochromatic laser pulses to investigate the resonant excitation of the amplitude and Leggett modes [55,56]. Interestingly, the analytical structure of the problem in Laplace space shares similarities with what we find in this paper. There are nevertheless important differences, since we consider interaction quenches and expand around the long-time asymptotic value of the gap.

For convenience, we briefly review our notation scheme: subscripts $i$ and $f$ denote the thermal equilibrium value before ($i$) and after ($f$) the quench. The subscript $\infty$ denotes the long-time asymptotic steady-state value of the gap. For example, $\Delta_{a,f}$ $(\Delta_{a,f})$ is the equilibrium value of gap $\alpha$ before (after) the quench, and $\Delta_{a,\infty}$ is its long-time asymptotic steady-state value following the time evolution governed by the BCS Hamiltonian. We note that our analysis is restricted to weak quenches, resulting in the system being in phase II, where the gap experiences Volkov-Kogan-like behavior.

### A. Linearized equations of motion

To analytically describe the postquench gap dynamics at long times, we generalize the method used first by Volkov and Kogan in Ref. [7]. Instead of expanding around the final equilibrium state $S_{a,f}^\infty$ and $\Delta_{a,f}$, however, we expand around the long-time nonequilibrium steady-state values $S_{a,\infty}^i$ and $\Delta_{a,\infty}$. Importantly, these steady-state values will be determined self-consistently in our calculation using Laplace’s final value theorem. We thus assume that in the long-time limit the superconducting gaps reach their long-time asymptotic values $\Delta_{a,\infty}$. Specifically, we expand the equations of motion and the gap equations around the asymptotic steady-state values

\[
S_{s}^i(\epsilon, t) = S_{s,\infty}^i(\epsilon) + g_{s}(\epsilon, t)
\]

\[
S_{a}^i(\epsilon, t) = S_{a,\infty}^i(\epsilon) + f_{a}(\epsilon, t)
\]

\[
\Delta_{a}(t) = \Delta_{a,\infty} + \delta_{a}(t),
\]

where, from the stationary condition of the equations of motion, $S_{s,\infty}^+ = S_{s,\infty}^-, S_{a,\infty}^+ = 0, \epsilon S_{a,\infty}^+ = -\Delta_{a,\infty} S_{a,\infty}^-$.

Note that $f_{a}$ describes pairing amplitude fluctuations and $g_{s}$ describes density fluctuations. The deviation of the gap from its long-time asymptotic value is denoted by $\delta_{a}$, which is determined by the pairing-amplitude fluctuations $f_{a}$ via the gap equation:

\[
\delta_{a}(t) = v_{f} \sum_{\beta} \gamma_{a\beta} \int_{-\Lambda}^{\Lambda} d\epsilon f_{\beta}(\epsilon, t),
\]

where $\gamma_{a\beta}$ is given in Eq. (4). As we will show below, because $f_{a}''$ is an odd function of $\epsilon$, $\delta_{a}$ is real, as long as we choose the initial equilibrium gaps of the two bands $\Delta_{a,i}$ to be real. With this in mind, we linearize the equations of motion by inserting Eqs. (13) into Eq. (11) to obtain

\[
f_{a}'' = 2 \epsilon f_{a}''
\]

\[
f_{a}'' = -2 \epsilon f_{a}'' - 2 \Delta_{a,\infty} \delta_{a} - 2 S_{a,\infty} \delta_{a}(t)
\]

\[
\delta_{a} = 2 \Delta_{a,\infty} f_{a}'',
\]

where $f_{a} = f_{a}'' + i f_{a}'''$ and the notation $f_{a}'' \equiv \frac{df_{a}}{d\epsilon}$ is used. Note that, as anticipated, $f_{a}'''$ remains an odd function of $\epsilon$ for all...
times, since $S_{\cdot,\infty}$ and $g_\alpha$ are odd while $f_\alpha'$ is even. As a result, the gap remains real for all times. The fact that the phases of the gaps are constants of motion follows directly from the particle-hole symmetry of the BCS Hamiltonian [12]. Therefore, the relative phase of the two gaps is also a constant of motion and the Leggett (relative phase) mode, which would in any case be overdamped in the regime we study here of interband pairing interaction only, is not excited in our quench protocol. In order to excite it, one must break the particle-hole symmetry of the BCS Hamiltonian [12].

The linearized equations of motion faithfully describe the long-time dynamics since at the long-time limit, the deviations from the asymptotic values are small, i.e., $(g_\alpha, f_\alpha, \delta_\alpha) \ll (S_{a,\infty}^2, S_{\alpha,\infty}, \Delta_{a,\infty})$. To have a better description of the gap dynamics over a wider time range, we focus on relatively weak quenches where $v_f/v_i$ is close to 1. In this case, the oscillations around $\Delta_{a,\infty}$ are small already at earlier times, allowing for a better comparison between numerics and analyses. Such weak quench regime is also the most relevant to experiments, where excess heating is suppressed.

Since we are interested in $\delta_\alpha$, which is only related to $f_\alpha$, see Eq. (14), we can further simplify the above equations by eliminating $g_\alpha$ to find

\[
\begin{align*}
J_\alpha''(s) + \frac{2sS_{\alpha,\infty}^2}{s^2 + 4E_{a,\infty}^2} J_\alpha(s) &= \frac{sJ_{\alpha,0}'}{s^2 + 4E_{a,\infty}^2} + \frac{2sS_{\alpha,\infty}^2}{s^2 + 4E_{a,\infty}^2} \delta_{\alpha,0} \\
J_\alpha'(s) - \frac{4sS_{\alpha,\infty}^2}{s^2 + 4E_{a,\infty}^2} J_\alpha(s) &= \frac{1}{8} \left[ J_{\alpha,0}' - \frac{4sS_{\alpha,\infty}^2}{s^2 + 4E_{a,\infty}^2} \delta_{\alpha,0} \right]
\end{align*}
\]

where $E_{a,\infty}^2 = \varepsilon^2 + \Delta_{a,\infty}^2$. Equations (16a) and (16b) describe the dynamics of the imaginary and real parts of the pairing amplitude fluctuations, respectively, which determine the time evolution of the gap.

**B. Solution in Laplace space**

To solve the differential equations (16a) and (16b), it is useful to perform a Laplace transformation $y(s) = \int_0^\tau y(t)e^{-st}dt$. We find the following algebraic equations:

\[
\begin{align*}
J_{\alpha,0}''(s) + \frac{2sS_{\alpha,\infty}^2}{s^2 + 4E_{a,\infty}^2} J_{\alpha,0}(s) &= \frac{sJ_{\alpha,0}'}{s^2 + 4E_{a,\infty}^2} + \frac{2sS_{\alpha,\infty}^2}{s^2 + 4E_{a,\infty}^2} \delta_{\alpha,0} \\
J_{\alpha,0}'(s) - \frac{4sS_{\alpha,\infty}^2}{s^2 + 4E_{a,\infty}^2} J_{\alpha,0}(s) &= \frac{1}{8} \left[ J_{\alpha,0}' - \frac{4sS_{\alpha,\infty}^2}{s^2 + 4E_{a,\infty}^2} \delta_{\alpha,0} \right]
\end{align*}
\]

Here, $s$ is the complex frequency in the Laplace domain and the subscript 0 indicates an initial condition, i.e., $f_{\alpha,0} \equiv f_\alpha(\varepsilon, t = 0^+)$, $\delta_{\alpha,0} \equiv \delta_\alpha(t = 0^+)$, etc. Physically, Eqs. (17a) and (17b) describe the phase and amplitude dynamics of the gap, respectively.

Since $\delta_{\alpha}$ and $f_{\alpha}$ are related through the gap equation (14), it is convenient to integrate both sides of the above equations over $\varepsilon$. Then, Eq. (17a) is trivially satisfied, since $S_{a,\infty}^2$ is an odd function of $\varepsilon$, by virtue of Eq. (10c), $J_{\alpha,0}'$ is an odd function of $\varepsilon$, by virtue of the second equation of (14).

Expressing $f$ in terms of $\delta$, and recasting Eq. (17b) in matrix form, the deviations of the superconducting gaps from their asymptotic values, $\delta_{\alpha}$, are given by:

\[
(\bar{\Phi}^\infty_{a}(s) + \bar{\mathcal{M}})\tilde{\delta}(s) = \frac{\bar{I}(s)}{s},
\]

where the hat (arrow) denote a matrix (vector) in band space. Here, we defined:

\[
\bar{\Phi}^\infty_{a\beta}(s) = \mathbb{I}_{a\beta} + 4\Delta_{a,\infty}^2 \left( \frac{S_{a,\infty}^2}{s^2 + 4E_{a,\infty}^2} \right) \bar{M}_{a\beta}(s)
\]

\[
\bar{\mathcal{M}}_{a\beta}(s) = (\hat{\varphi}^{-1})_{a\beta} - \mathbb{I}_{a\beta} \left( \frac{S_{a,\infty}^2}{\Delta_{a,\infty}} \right),
\]

where $\mathbb{I}$ is the identity matrix in band space and the following notation is used:

\[
\langle \ldots \rangle = v_f \int d\varepsilon \langle \ldots \rangle.
\]

For convenience, we write $\bar{\Phi}^\infty_{a\beta}(s) \equiv \mathbb{I}_{a\beta} \bar{\Phi}^\infty_{a}$ and define:

\[
\bar{\Phi}^\infty_{a}\equiv (s^2 + 4\Delta_{a,\infty}^2) \left( \frac{S_{a,\infty}^2}{s^2 + 4E_{a,\infty}^2} \right).
\]

The function $\bar{I}(s)$ on the right-hand side is given by (detailed derivation in Appendix A)

\[
I_{a}(s) = \sum_{\rho} \langle \hat{\varphi}^{-1} \rangle_{a\rho} \delta_{\rho,0} + (\Delta_{a,i} - \Delta_{a,\infty})
\]

\[
\times \left[ \bar{\Phi}^{\infty}_{a}(s) - \frac{\bar{I}_{f}(s)}{v_i} \sum_{\rho} \langle \hat{\varphi}^{-1} \rangle_{a\rho} \frac{\Delta_{\beta,i}}{\Delta_{a,i}} \right],
\]

with:

\[
\bar{\Phi}^{\infty}_{a}(s) = (s^2 + 4\Delta_{a,\infty}^2) \left( \frac{S_{a,\infty}^2}{s^2 + 4E_{a,\infty}^2} \right).
\]

The solution for $\tilde{\delta}(s)$ in Laplace space is then simply given by

\[
\tilde{\delta}(s) = (\bar{\Phi}^\infty(s) + \bar{\mathcal{M}})^{-1}\bar{I}(s).
\]

It is clear that without interband interaction, $V = 0$, $\bar{\mathcal{M}}_{a\beta}$ becomes a diagonal matrix, since $\bar{g}_{a\beta} \in$ Eq. (4) is diagonal. As a result, Eq. (18) becomes diagonal in band space as well, and the two-band model reduces to two independent one-band models.

In the following sections, we will extract the dynamics of the gaps in the long-time limit from their analytic behaviors in Laplace space. These are determined by the functions $\bar{\Phi}^\infty(s)$ and $\bar{I}(s)$, as they are the only $s$-dependent functions in Eq. (18). Their $s$ dependence comes from the two functions $\bar{\Phi}^\infty_{a}(s)$ and $\bar{\Phi}^{\infty}_{a}(s)$ defined above.

The function $\bar{\Phi}^\infty_{a}(s)$ is straightforward to calculate since the initial pseudospin configuration is given by the equilibrium value of the gap at $T = 0$, i.e., $S_{a,\infty}/\Delta_{a,i} = \frac{1}{2\sqrt{\varepsilon^2 + \Delta_{a,i}^2}}$. Inserting this initial pseudospin state into Eq. (24), this can be brought to the form

\[
\bar{\Phi}^\infty_{a}(s) = \frac{s}{2\Delta_{a,\infty}},
\]
where we defined the dimensionless ratio \( \tilde{\Delta}_{\alpha,i} = \Delta_{\alpha,i}/\Delta_{\alpha,\infty} \) and the function

\[
\Upsilon(\Delta, x) = v_f \frac{\sqrt{\frac{\Delta^2 + 1}{\Delta^2}} \arccos \left( \sqrt{\frac{\Delta^2 + 1}{\Delta^2}} \right)}{\sqrt{1 - \frac{4x^2}{\Delta^2}}}.
\]

To find an explicit expression for \( \Phi_\alpha^\infty(s) \), given by Eq. (22), we first need to compute the function \( S^\infty_{\alpha,\infty}/\Delta_{\alpha,\infty} \). The gap equation [see Eq. (6)], which is satisfied regardless of whether the system is in thermal equilibrium or not, restricts the expectation value of this quantity to:

\[
\left\langle \frac{S^\alpha_{1,\infty}}{\Delta_{1,\infty}} \right\rangle = \eta \left\langle \frac{S^\alpha_{2,\infty}}{\Delta_{1,\infty}} \right\rangle = -1.
\]

As we discussed above, the nonzero interband interactions render the matrix \( \mathbf{M} \) off-diagonal and make the two-band model fundamentally different than the single-band case. While a generic discussion of arbitrary inter- and intraband interactions is possible, the analysis is simplified considerably by focusing on the case of interband repulsion only, i.e., \( r = 0 \). Indeed, our numerical results discussed in Fig. 4 show that the general behavior of the two-band problem is the same for \( r = 0 \) and \( r \neq 0 \). Note that in iron-based superconductors, the intraband pairing interaction is believed to be much larger than the interband interaction due to an enhancement mediated by antiferromagnetic fluctuations [41]. Setting \( r = 0 \) in Eq. (4) yields an off-diagonal matrix \( \hat{\gamma} = \begin{pmatrix} 0 & -\eta \\ -\eta & 0 \end{pmatrix} \). As a result, the equation above becomes:

\[
\left\langle S^1_{1,\infty} / \Delta_{1,\infty} \right\rangle = \eta \left\langle S^2_{1,\infty} / \Delta_{1,\infty} \right\rangle = -1.
\]

Note that this ratio involves the pseudospin of band \( \alpha \) and the gap of the other band \( \tilde{\alpha} \), where \( \tilde{\alpha} = 1(2) \) for \( \alpha = 2(1) \). To proceed, we note that, in equilibrium, the same relationship holds between the ratios of the pseudospin and the gap:

\[
\left\langle S^\alpha_{1,\infty} / \Delta_{1,\infty} \right\rangle = \eta \left\langle S^\alpha_{2,\infty} / \Delta_{1,\infty} \right\rangle = -1.
\]

The difference is that, in equilibrium, from Eq. (10), we know precisely the expression for \( S^\alpha_{1,\infty} / \Delta_{1,\infty} \):

\[
\left\langle S^\alpha_{1,\infty} / \Delta_{1,\infty} \right\rangle = \eta \left\langle S^\alpha_{2,\infty} / \Delta_{1,\infty} \right\rangle = \frac{\Delta_{1,\infty}}{2\sqrt{\epsilon^2 + \Delta_{1,\infty}^2}}.
\]

\[
\eta \left\langle S^\alpha_{2,\infty} / \Delta_{1,\infty} \right\rangle = \eta \left\langle \frac{\Delta_{1,\infty}}{2\sqrt{\epsilon^2 + \Delta_{1,\infty}^2}} \right\rangle = -1.
\]

Based on this similarity, we propose the following ansatz:

\[
\frac{S^\alpha_{1,\infty}}{\Delta_{1,\infty}} = \frac{\tilde{\Delta}_{1,\infty}}{\Delta_{1,\infty}} \left( \frac{1}{2\sqrt{\epsilon^2 + \tilde{\Delta}_{1,\infty}^2}} \right).
\]

where \( \tilde{\Delta}_{1,\infty} = \Delta_{1,\infty}/\Delta_{1,\infty} \) is defined analogously to \( \tilde{\Delta}_{1,1} \). Clearly, this ansatz satisfies the constraint (29). For \( r \neq 0 \), the constraint will likely have a more complicated form; thus, for the sake of clarity, we focus on the case \( r = 0 \). We will verify the validity of this ansatz later by an explicit comparison to numerical calculations and by comparison with the exact solution of the single-band case. For now, we proceed with this ansatz and perform the energy integration in the expression of \( \Phi_\alpha^\infty(s) \). We obtain:

\[
\Phi_\alpha^\infty(s) = \frac{\tilde{\Delta}_{1,\infty}}{\tilde{\Delta}_{1,\infty}} \Upsilon \left( \frac{\tilde{\Delta}_{1,\infty}}{\Delta_{1,\infty}} \right). \quad (33)
\]

C. Asymptotic gap values

In this section, we show how to extract the long-time asymptotic steady-state gap values \( \Delta_{\alpha,\infty} \) self-consistently. To set the stage, and validate the ansatz proposed in the previous subsection, we first present the calculation for the single-band case, comparing the perturbative solution with the exact one.

1. Asymptotic gap for the single-band model

In the single-band BCS model with attractive pairing interaction \( u \equiv U N \), a quench suddenly changes the pairing interaction \( u_i \rightarrow u_{ij} \). It is convenient to use \( \Delta_i / \Delta_f \) as the quench parameter, where \( \Delta_i (\Delta_f) \) is the equilibrium value of the gap with pairing interaction \( u_i (u_f) \). We employ the same linearization scheme for the single-band model as above in Eqs. (13)–(15) for the two-band case, and expand around the long-time asymptotic values, \( S^\infty_\alpha \) and \( \Delta_{\alpha,\infty} \). The equation for the gap deviation \( \delta \) in Laplace space, Eq. (18), becomes in the single-band case:

\[
\delta(s) = -\left(1 - \frac{u_f}{u_i}\right) \frac{\Delta_{\infty}}{s\Phi_i(s)} + (\Delta_i - \Delta_{\infty}) \frac{\Phi_i(s)}{s\Phi_i(s)}.
\]

where

\[
\Phi_i(s) = \left( \frac{s^2 + 4\Delta_{\infty}^2}{s^2 + 4\Delta_i^2} \right) \Delta_i.
\]

\[
\Phi_{\infty}(s) = \left( \frac{s^2 + 4\Delta_{\infty}^2}{s^2 + 4\Delta_f^2} \right) \Delta_{\infty}.
\]

Here, \( S^\alpha_i / \Delta_i = 1/(2E_i) \) with \( E_i = \sqrt{\epsilon^2 + \Delta_i^2} \) is given by its value in the initial \( T = 0 \) ground state prior to the quench. The ratio \( S^\infty_\alpha / \Delta_{\infty} \), according to our ansatz (32), becomes in the single-band case:

\[
\frac{S^\infty_\alpha}{\Delta_{\infty}} = \frac{1}{2\sqrt{\epsilon^2 + \Delta_f^2}}. \quad (36)
\]

This ansatz can be recast in an alternative way as an ansatz for the nonequilibrium distribution function. From the definition of \( S^\alpha_j \), Eq. (10), we have:

\[
S^\alpha_j = \frac{\Delta_f n_0(\epsilon)}{2\sqrt{\epsilon^2 + \Delta_f^2}}. \quad (37)
\]

where we defined the equilibrium distribution function \( n_0(\epsilon) = \tanh[\sqrt{\epsilon^2 + \Delta_f^2}/(2T)] \). From the gap equation, it follows that \( \left\langle S^\alpha_j \right\rangle = 1 \). Analogously, we can express \( S^\infty_\alpha \) in terms of the nonequilibrium quasiparticle distribution function \( n_{\text{eff}}(\epsilon) \):

\[
S^\infty_\alpha = \frac{\Delta_{\infty} n_{\text{eff}}(\epsilon)}{2\sqrt{\epsilon^2 + \Delta_{\infty}^2}}. \quad (38)
\]
Because the gap equation has to be satisfied also in nonequilibrium, it follows that:

\[
\left\langle \frac{S_\infty^s}{\Delta_\infty} \right\rangle = \left(\frac{n_{\text{eff}}(\varepsilon)}{2\sqrt{\varepsilon^2 + \Delta_\infty^2}}\right) = 1.
\]  

(39)

The ansatz (36) thus can be recast as an ansatz for the effective nonequilibrium distribution function:

\[
n_{\text{eff}}(\varepsilon) = n_0(\varepsilon) \frac{\sqrt{\varepsilon^2 + \Delta_\infty^2}}{\varepsilon^2 + \Delta_j^2}.
\]  

(40)

Having obtained an explicit expression for \(S_\infty^s/\Delta_\infty\), we can derive analytic expressions for \(\Phi_j(s)\) and \(\Phi_\infty(s)\):

\[
\Phi_j(\infty)(s) = u_f \frac{\sqrt{s^2 + 4\Delta_j^2} \arccos \left(\frac{s^2 + 4\Delta_j^2}{2|\Delta_j|}\right)}{\sqrt{4(\Delta_j^2 - \Delta_\infty^2) - s^2}}.
\]  

(41)

To find the long-time asymptotic value of the gap, we use the self-consistency condition that \(\lim_{t \to \infty} \Delta(t) = \Delta_\infty\), or equivalently, \(\lim_{s \to \infty} \delta(s) = 0\). Using the final value theorem in Laplace space (see, e.g., Ref. [58] and references therein), this condition becomes

\[
\lim_{s \to \infty} \delta(s) = 0.
\]  

(42)

Using Eq. (34) and inserting the explicit expressions from Eq. (41), we find that the asymptotic value of the gap \(\Delta_\infty\) must satisfy

\[
\sqrt{\Delta_j^2 - \Delta_\infty^2} \arccos \left(\frac{\Delta_j^2 - \Delta_\infty^2}{2\Delta_j}\right) \ln \left(\frac{\Delta_j}{\Delta_j - \Delta_\infty} \arccos \left(\frac{\Delta_\infty}{\Delta_j}\right) \sqrt{1 - \frac{\Delta_\infty^2}{\Delta_j^2}}\right) = 0.
\]  

(43)

It is straightforward to show that this equation is identical to the one that emerges in the exact solution of the single-band BCS gap dynamics using the method of the Lax vector [11,12]. In Fig. 5, we compare the results from both methods, which match perfectly. Interestingly, in phase III (persistent oscillations), our method gives the average value of \(\Delta_1/f\). As shown in Fig. 6, we find that, in the case of pure interband interactions (\(r = 0\)), the ratios between the

\[
\begin{align*}
\Delta_1/\Delta_f & = \frac{\Delta_1/\Delta_f}{\Delta_1/\Delta_f} \\
\Delta_2/\Delta_f & = \frac{\Delta_2/\Delta_f}{\Delta_2/\Delta_f} \\
\Delta_3/\Delta_f & = \frac{\Delta_3/\Delta_f}{\Delta_3/\Delta_f}
\end{align*}
\]  

FIG. 6. Asymptotic values of the gaps in the two band case as a function of the interaction quench parameter \(\Delta_1/\Delta_f\). The dashed gray line is the result for the single-band BCS model. For the two-band model, we use \(\Delta_1/\Delta_1/f\) as the quench parameter, and we choose the ratio between the density of states to be \(\eta = 0.8\).
asymptotic and final equilibrium gaps $\Delta_{a,\infty}/\Delta_{a,f}$ are, to a very good approximation (i.e., with a numerical deviation of less than 0.01%), equal for both bands, i.e., $\Delta_{1,f} = \Delta_{2,f}$. They are also identical to the single-band ratio if we adjust the definition of the quench amplitude accordingly, such that the $x$ axis corresponds to $\Delta_1/\Delta_f$ in the single-band case and to $\Delta_{1,f}/\Delta_{1,\infty}$ in the two-band case.

Using the result obtained here that $\Delta_{1,f} = \Delta_{2,f}$, the prefactor of Eq. (33) becomes 1. Thus, both $\Phi^\omega(s)$ and $\Phi^\omega_i(s)$ have the same functional dependence: $\Phi^\omega_i(s) = \gamma(\Delta_{a,f}, \sqrt{s/2\Delta_{a,\infty}})$, $\Phi^\omega(s) = \gamma(\Delta_{a,i}, \sqrt{s/2\Delta_{a,\infty}})$.

D. Damped gap oscillations in the long-time limit

The long-time behavior of the gap in the time domain $\Delta(t)$ can be obtained by applying the inverse Laplace transformation to Eq. (44). In order to perform the inverse Laplace transformation, we first need to study the analytical behavior of the solution in Laplace space and find its poles and branch cuts. They are determined by the analytic properties of the function $\gamma(\Delta, x)$, defined in Eq. (27) and repeated here for convenience:

$$\gamma(\Delta, x) = v_f \sqrt{\frac{1}{\pi \Delta}} \arccos\left(\sqrt{\frac{1}{\pi \Delta}}\right).$$

(46)

The reason why only the analytical properties of $\gamma(\Delta, x)$ matter is because we can express both $\Phi^\omega_i(s)$ and $\Phi^\omega(s)$ in terms of this function:

$$\Phi^\omega_i(s) = \gamma(\Delta_{a,i}/f, z)$$

(47a)

$$\Phi^\omega(s) = \gamma(\Delta_{a,i}/f, \kappa z),$$

(47b)

where $z = \frac{s}{2\Delta_{a,\infty}}$, $\Delta_{a,i}/f = \frac{\Delta_{a,i}}{2\Delta_{a,\infty}}$, and $\kappa = \frac{\Delta_{a,i}}{2\Delta_{a,\infty}}$. For concreteness, in this section we consider the gap with $a = 1$ to be the one that is asymptotically smaller, implying that $|\kappa| < 1$. But note that our results can be straightforwardly applied also to the case $|\kappa| > 1$.

The function $\gamma(\Delta, z)$ has two branch cuts, one between $(-i\infty, -i)$ and another one between $(i, i\infty)$. The function is analytic elsewhere. Applying the Cauchy’s residue theorem (see Appendix C and Fig. 9 for details), we convert the Bromwich integral into four integrals along the sides of the two branch cuts. Note that we have already eliminated the pole at the origin by imposing the final value theorem in Sec. IV C 1. In addition, we also use the following properties of the function $\gamma$:

$$\gamma(\Delta, z) = \gamma(\Delta, -z)$$

(48a)

$$\text{Re}[\gamma(\Delta, 0^+ + iy)] = \text{Re}[\gamma(\Delta, 0^- + iy)], \text{ for } y > 1$$

(48b)

$$\text{Im}[\gamma(\Delta, 0^+ + iy)] = -\text{Im}[\gamma(\Delta, 0^- + iy)], \text{ for } y > 1.$$  

(48c)

As a result, the inverse Laplace transformation is given by the following integral:

$$\delta_{a}(t) = \frac{2}{\pi} \int_{i}^{i\infty} \text{Im}[\delta_{a}(z)] \frac{\cosh(2\Delta_{a,\infty} z t)}{z} dz,$$

(49)

$$\text{D(z)} = \gamma(\Delta_{1,f}, z)\gamma(\Delta_{2,f}, \kappa z) + \frac{1}{\kappa} \gamma(\Delta_{1,f}, \kappa z)$$

(51)

In the long-time limit, where $2\Delta_{1,f}\gg 1$, the integrand of Eq. (49) is highly oscillatory. Only singular behaviors of $\text{Im}[\delta_{a}(z)]$ will therefore make a contribution to the long-time dynamics of the superconducting gap. Indeed, $\text{Im}[\delta_{a}(z)]$ has two branch points along $z \in [i, i\infty)$: one is located at $z = i$ and the other one is located at $z = i/|\kappa|$. We expand $\text{Im}[\delta_{a}(z)]$ near these two branch points, i.e., $z = i + i\epsilon$ and $z = i/|\kappa| \pm i\epsilon$, and find that both exhibit $\sqrt{\epsilon}$ behavior [details shown in Appendix B]. This is sharply distinct from the single-band case, where only one branch point is present along $z \in [i, i\infty)$. More importantly, the asymptotic behavior in the vicinity of the branch point in the single-band case is $1/\sqrt{\epsilon}$ rather than $1/\sqrt{\epsilon}$. The two cases are plotted and compared in Fig. 7. The $1/\sqrt{\epsilon}$ behavior leads to a $t^{-1/2}$ decay of the gap.
The ratio between the densities of states of the two bands is set to be \( \eta \). In contrast, the \( \sqrt{\epsilon} \) behavior in Laplace space leads to a faster \( r^{-3/2} \) decay in the two-band model

\[
\int_{1}^{\infty} \frac{\sqrt{y-1}}{y} \cos[y(2\Delta t)]dy \simeq -\frac{\sqrt{\pi}}{2(2\Delta t)^{3/2}} \quad (52)
\]

for \( 2\Delta t \gg 1 \) (details are shown in Appendix C). The damping of the gap oscillations thus occurs faster for two-band superconductivity.

To find the full long-time expressions of the gap, including prefactors and oscillatory factors, we perform a careful asymptotic analysis of \( \text{Im}[\tilde{\zeta}_g(z)] \). The final result for the long-time gap oscillations reads:

\[
\Delta_1(t) \simeq \Delta_{1,\infty} + A_1 \frac{\sin (2\Delta_{1,\infty} t + \frac{\pi}{4})}{(\Delta_{1,\infty} t)^{3/2}} + B_1 \frac{\sin (2\Delta_{2,\infty} t - \frac{\pi}{4})}{(\Delta_{2,\infty} t)^{3/2}} + C_1 \frac{\sin (2\Delta_{1,\infty} t + \frac{\pi}{4})}{(\Delta_{1,\infty} t)^{3/2}}
\]

\[
\Delta_2(t) \simeq \Delta_{2,\infty} + A_2 \frac{\sin (2\Delta_{1,\infty} t - \frac{\pi}{4})}{(\Delta_{2,\infty} t)^{3/2}} + B_2 \frac{\sin (2\Delta_{1,\infty} t - \frac{\pi}{4})}{(\Delta_{1,\infty} t)^{3/2}} + C_2 \frac{\sin (2\Delta_{1,\infty} t + \frac{\pi}{4})}{(\Delta_{1,\infty} t)^{3/2}}
\]

(53a)

(53b)

where the prefactors \( A_g, B_g, \) and \( C_g \) are calculated from the asymptotic analysis and explicitly shown in Appendix B. The gap oscillation frequencies are determined by the asymptotic values of the gaps in the two different bands \( \Delta_{g,\infty} \). As discussed in the previous sections, the asymptotic values of the gaps are determined by the quench amplitude \( \Delta_{a,i}/\Delta_{a,f} \) and the ratio of the density of states \( \eta \) between the two bands. In general, they will also depend on \( r = -U/V \), which we have set to zero for simplicity here. The same holds for the prefactors of the sinusoidal oscillations.

In Fig. 8, we compare our analytical results to the numerical solution of the equations of motion for two different weak quench amplitudes in phase II. We find an excellent quantitative agreement between the two, which also justifies our analytical ansatz a posteriori.

We finish this section by commenting on how our solution gives the known single-band result in the limit where the ratio between the two densities of states approaches one, \( \eta \to 1 \). In this limit, the gaps have the same asymptotic magnitude, i.e., \( \Delta_{1,\infty} = \Delta_{2,\infty} \). The equilibrium gaps also have the same magnitude, leading to \( \gamma(\tilde{\Delta}_{a,i/f}, z) = \gamma(\tilde{\Delta}_{a,i/f}, z) = \gamma(\Delta_{a,i/f}, z) \). As a result, Eq. (50) becomes

\[
\frac{2\delta_a(z)}{2\Delta_{a,\infty}} = \left[ \frac{1}{2} \left( \frac{v_f}{v_i} - 1 \right) + \frac{(\tilde{\Delta}_{a,f} - 1)}{2} \gamma(\tilde{\Delta}_{a,f}, z) \right] \frac{[\gamma(\Delta_{a,f}, z) - 2]}{D(z)}
\]

(54)

where \( D(z) = \gamma^2(\tilde{\Delta}_{a,f}, z) - 2\gamma(\tilde{\Delta}_{a,f}, z) \). Further simplification of the above equation gives:

\[
\frac{2\delta_a(z)}{2\Delta_{a,\infty}} = \left[ \frac{1}{2} \left( \frac{v_f}{v_i} - 1 \right) \right] \gamma(\Delta_{a,f}, z) + \frac{1}{2} \gamma(\tilde{\Delta}_{a,i}, z) + \frac{1}{2} \gamma(\tilde{\Delta}_{a,f}, z)
\]

(55)

In writing this last equation, we used the fact that \( \gamma(\Delta_{a,f}, z) = \gamma(\tilde{\Delta}_{a,f}, z) \). This is the same expression as the solution of the single-band case in Laplace space, Eq. (34).
Using the asymptotic behavior of $\Gamma(\Delta_{a}, iy)$ near the branch point $y \rightarrow 1$ [details shown in Appendix B, see Eq. (B1)], we arrive at the following asymptotic behavior:

$$\text{Im}[iy\delta_{a}(y)] \simeq \frac{\nu_{f}^{-1} - \nu_{i}^{-1}}{\pi} |\Delta_{a,j}| \sqrt{\frac{2}{y - 1}}.$$  \hspace{1cm} (56)

By applying the inverse Laplace transformation, we find that the gap dynamics is characterized by oscillations with frequency $2\Delta_{c}$ and $t^{-1/2}$ damping:

$$\Delta_{a}(t) \simeq \Delta_{c, \infty} + \left(\frac{2}{\pi}\right)^{3/2} \Delta_{a,j} \ln \left(\frac{\Delta_{a,i}}{\Delta_{a,f}}\right) \cos\left(2\Delta_{c} \sqrt{\frac{\nu_{f}^{-1} - \nu_{i}^{-1}}{\pi}} \frac{t}{\sqrt{2\Delta_{c}}}\right).$$  \hspace{1cm} (57)

V. CONCLUSIONS

In this paper, we developed a generalization of the Volkov-Kogan Laplace-space analysis for the postquench dynamics of s-wave BCS superconductors in the collisionless regime [7], and applied it to interaction quenches of two-band BCS superconductors. We showed that the two-band case is fundamentally different from the single-band case. Not only do the gap oscillations display beating associated with the two different gap values on the two bands, but they also display a faster $t^{-3/2}$ power-law damping, as opposed to the $t^{-1/2}$ damping of the single-band case. For weak quenches, our analytical results agree very well with the numerical results in the long-time limit, demonstrating that the gap dynamics of multiband systems cannot be simply decomposed into the sum of the gap dynamics of single-band systems. Formally, this new power-law decay can be understood as arising from the splitting of the relevant branch point in Laplace space in two, as shown in Fig. 7. As a result, one expects the same $t^{-3/2}$ behavior to take place even when the number of bands is larger than 2. From a more physical perspective, the stronger damping in the two-band case arises because the Cooper-pairs dephasing involves states from both bands due to the interband coupling. Such a dephasing leading to $t^{-3/2}$ instead of $t^{-1/2}$ is thus intrinsic to multiband systems and independent on the quench amplitude.

From a methodological viewpoint, our analysis is distinct from the one introduced by Volkov and Kogan [7] (see also the more recent works by Yuzbashyan and coworkers [32,34]), because we linearize the equations of motion around the asymptotic long-time pseudospin states as opposed to the final equilibrium states. This allows us to self-consistently determine the asymptotic long-time steady-state values of the gaps over the full range of quench amplitudes in phase II (and phase I, where the steady-state gaps vanish). We explicitly showed that the self-consistent equation for the steady-state gap in the single-band case agrees with the exact expression derived within the Lax vector analysis [10–12]. Like in the two-band model we investigate here, our method can be very useful in cases where an exact solution is not (yet) available, for example, to investigate quenches towards more exotic fully gapped pairing states such as $s + is$ or $s + id$. Other interesting future directions are to include a finite intraband pairing interaction $r \neq 0$, competing electronic order parameters such as spin-density waves [59], or generalize and apply our Laplace method to study quenches in superconductors with a nodal gap structure such as those with $d$-wave symmetry [60].

APPENDIX A: INITIAL CONDITIONS FOR THE INTERACTION QUENCH

The system is at equilibrium before the interaction quench. For systems with only interband repulsion, the superconducting gap is given by

$$\Delta_{1,j} = -v_{j} \eta \int d\varepsilon \frac{\Delta_{2,j}}{2 \sqrt{\varepsilon^{2} + \Delta_{1,j}^{2}}} \quad \text{(A1a)}$$

$$\Delta_{2,j} = -v_{i} \int d\varepsilon \frac{\Delta_{1,j}}{2 \sqrt{\varepsilon^{2} + \Delta_{1,j}^{2}}} \quad \text{(A1b)}$$

where $v_{i} = V_{i} N_{1} / N_{1}$ is the dimensionless interband repulsion, and $\eta = N_{2} / N_{1}$ is the ratio between the density of states...
are seven terms that determine the analytic behavior of the gap. The branch points all come from the function \( \Upsilon \)

\[ \text{Postquench Gap Dynamics of Two-Band ... Physical Review B} \]

After the interaction quench, the interband repulsion is suddenly changed to a different value, \( v_f \). The initial conditions of the postquench dynamics of the superconducting gaps are thus given by replacing the interband repulsion with its postquench value \( v_f \).

\[ \Delta_1(0^+) = -v_f \eta \int d\epsilon \frac{\Delta_{2,i}}{2\sqrt{\epsilon^2 + \Delta_{2,i}^2}} = \frac{v_f}{v_i} \Delta_{1,i} \]  

(A3a)

\[ \Delta_2(0^+) = -v_f \int d\epsilon \frac{\Delta_{1,i}}{2\sqrt{\epsilon^2 + \Delta_{1,i}^2}} = \frac{v_f}{v_i} \Delta_{2,i} \]  

(A3b)

Substituting in the linearized equations (13) and (15), the initial conditions on the pseudospin deviations \( f_a \) become

\[ f_{a,0} = 0 \]  

(A4a)

\[ f''_{a,0} = \frac{-\epsilon(\Delta_{a,i} - \Delta_{a,\infty})}{\sqrt{\epsilon^2 + \Delta_{a,i}^2}} - 2\delta_{\alpha,0} S_{a,i}. \]  

(A4b)

We recall that \( f''_{a,0} \) and \( f'''_{a,0} \) are related to the dynamics of the superconducting gap in Laplace space via \( L_s(s) = \frac{2e^{i\pi f''_{a,0} + f'''_{a,0}}}{s^2 + \Delta_{a,\infty}^2} \), which yields Eq. (23).

**APPENDIX B: ASYMPTOTIC ANALYSIS OF THE SUPERCONDUCTING GAP IN LAPLACE SPACE**

In this Appendix, we analyze the asymptotic behavior of the gap in Laplace space near the branch points. From Eq. (50), there are seven terms that determine the analytic behavior of the gap. The branch points all come from the function \( \Upsilon(\Delta, z) \), which opens branch cuts at \((-i\infty, -i)\) and \((i, i\infty)\), as shown in Fig. 9. Let \( z = iy \), then, around \( y = 1 \), we have

\[ \Upsilon(\Delta, y) \simeq \begin{cases} \frac{v_{f,\pi}}{|\Delta|} \sqrt{\frac{1}{2}} - O(1 - y), & y \to 1 - \epsilon \\ \frac{v_{f,\pi}}{|\Delta|} \sqrt{\frac{1}{2}} + O(y - 1), & y \to 1 + \epsilon \end{cases} \]  

(B1)

where \( \epsilon \) is an infinitesimal positive number.

We use the asymptotic behavior of \( \Upsilon(\Delta, y) \) to expand all the terms in Eq. (50), and obtain the following results:

\[ \text{Im} \left[ \frac{1}{D(y)} \right] \simeq \frac{2}{\epsilon} \text{Im} \left[ \frac{\frac{\Upsilon_{\Delta,2}}{\Upsilon(\Delta_{1,1})}}{\Delta_{1,1}} \right] + \frac{v_{f,\pi}}{|\Delta_{1,1}|} \sqrt{\frac{1}{2}}, \quad y \to 1 + \epsilon \]

\[ \text{Im} \left[ \frac{\Upsilon(\Delta, y)}{D(y)} \right] \simeq \frac{v_{f,\pi}}{|\Delta_{1,1}|} \sqrt{\frac{1}{2}}, \quad y \to 1 + \epsilon \]

\[ \text{Im} \left[ \frac{\Upsilon(\Delta_{1,1})}{D(y)} \right] \simeq \frac{v_{f,\pi}}{|\Delta_{1,1}|} \sqrt{\frac{1}{2}}, \quad y \to 1 + \epsilon \]

\[ \text{Im} \left[ \frac{\Upsilon(\Delta_{2,1})}{D(y)} \right] \simeq \frac{v_{f,\pi}}{|\Delta_{2,1}|} \sqrt{\frac{1}{2}}, \quad y \to 1 + \epsilon \]

\[ \text{Im} \left[ \frac{\Upsilon(\Delta_{2,2})}{D(y)} \right] \simeq \frac{v_{f,\pi}}{|\Delta_{2,2}|} \sqrt{\frac{1}{2}}, \quad y \to 1 + \epsilon \]

\[ \text{Im} \left[ \frac{\Upsilon(\Delta_{2,3})}{D(y)} \right] \simeq \frac{v_{f,\pi}}{|\Delta_{2,3}|} \sqrt{\frac{1}{2}}, \quad y \to 1 + \epsilon \]

\[ \text{Im} \left[ \frac{\Upsilon(\Delta_{2,4})}{D(y)} \right] \simeq \frac{v_{f,\pi}}{|\Delta_{2,4}|} \sqrt{\frac{1}{2}}, \quad y \to 1 + \epsilon \]
\[
\text{APPENDIX C: INVERSE LAPLACE TRANSFORMATION AND USEFUL INTEGRALS}
\]

The inverse Laplace transformation is given by the Bromwich integral:
\[
y(t) = \mathcal{L}^{-1}[Y](t) = \frac{1}{2\pi i} \int_{\sigma-i\infty}^{\sigma+i\infty} Y(s)e^{st} \, ds,
\]
where \( \sigma \) is a real number that is larger than the real parts of all the singularities of \( Y(s) \).

All the asymptotic behaviors of the gap in Laplace space are square-root-like. Consequently, transforming back to real time domain leads to a \( t^{-3/2} \) decay.

\[
\int_{1}^{\infty} \frac{\sqrt{y-1}}{y} \cos(2\Delta_{1,\infty}yt) \, dy = \sqrt{\frac{\pi}{4\Delta_{1,\infty}\frac{1}{|\Delta_{1,\infty}|}}} \left[ \cos(2\Delta_{1,\infty}t) - \sin(2\Delta_{1,\infty}t) \right] + \pi \left[ C \left( \sqrt{\frac{4\Delta_{1,\infty}}{\pi}} \right) + S \left( \sqrt{\frac{4\Delta_{1,\infty}}{\pi}} \right) - 1 \right]
\]

\[
\simeq -\sqrt{\pi} \sin \left( 2\Delta_{1,\infty}t + \frac{\pi}{4} \right) \frac{2(2\Delta_{1,\infty})^{3/2}}{(2\Delta_{1,\infty})^{3/2}}
\]

for \( 2\Delta_{1,\infty} \gg 1 \). Similarly, \( \int_{-\infty}^{1} \frac{\sqrt{1-|\kappa|y}}{y} \cos(2\Delta_{2,\infty}yt) \, dy \simeq -\sqrt{\pi} \sin \left( 2\Delta_{2,\infty}t - \frac{\pi}{4} \right) \frac{2(2\Delta_{2,\infty})^{3/2}}{(2\Delta_{2,\infty})^{3/2}} \).
\[
\frac{A_2}{\Delta_{2,\infty}} = -\frac{\sqrt{\pi}}{4} \left( \frac{v_f}{v_i} \frac{\Delta_{1,i}}{\Delta_{2,i}} - 1 + \frac{\Delta_{1,f}}{\Delta_{1,i}} \right) \frac{1}{\gamma(\Delta_{2,f}, \kappa)} + \frac{\kappa}{\eta} \frac{v_f}{v_i} \left( \frac{\Delta_{1,i}}{\Delta_{2,i}} + \frac{\Delta_{2,i}}{\Delta_{1,i}} \right) - 2 \right] \frac{1}{\gamma^2(\Delta_{2,f}, \kappa)} \right) \]

\[
\frac{B_2}{\Delta_{2,\infty}} = -\frac{\sqrt{\pi}}{4} \left[ \frac{v_f}{v_i} \left( \frac{\Delta_{1,i}}{\Delta_{2,i}} + \frac{\Delta_{2,i}}{\Delta_{1,i}} \right) - 2 \right] \frac{1}{\gamma(\Delta_{1,f}, \kappa)} \right) \]

\[
\frac{C_2}{\Delta_{2,\infty}} = -\frac{\sqrt{\pi}}{4} \left[ \frac{v_f}{v_i} \left( \frac{\Delta_{1,i}}{\Delta_{2,i}} + \frac{\Delta_{2,i}}{\Delta_{1,i}} \right) - 2 \right] \frac{1}{\gamma(\Delta_{1,f}, \kappa)} \right) \]

Correction: The original Figs. 3(a), 3(b), 3(e), 3(f), and 4(a) were processed improperly during the initial production cycle and have been resolved.
